Chapter 10

Correlation and Regression

Outline

10–1 Introduction
10–2 Scatter Plots
10–3 Correlation
10–4 Regression
10–5 Coefficient of Determination and Standard Error of the Estimate
10–6 Multiple Regression (Optional)
10–7 Summary

Objectives

After completing this chapter, you should be able to

1. Draw a scatter plot for a set of ordered pairs.
2. Compute the correlation coefficient.
3. Test the hypothesis $H_0: \rho = 0$.
4. Compute the equation of the regression line.
5. Compute the coefficient of determination.
6. Compute the standard error of the estimate.
7. Find a prediction interval.
8. Be familiar with the concept of multiple regression.
Do Dust Storms Affect Respiratory Health?

Southeast Washington state has a long history of seasonal dust storms. Several researchers decided to see what effect, if any, these storms had on the respiratory health of the people living in the area. They undertook (among other things) to see if there was a relationship between the amount of dust and sand particles in the air when the storms occur and the number of hospital emergency room visits for respiratory disorders at three community hospitals in southeast Washington. Using methods of correlation and regression, which are explained in this chapter, they were able to determine the effect of these dust storms on local residents.

In previous chapters, two areas of inferential statistics—hypothesis testing and confidence intervals—were explained. Another area of inferential statistics involves determining whether a relationship between two or more numerical or quantitative variables exists. For example, a businessperson may want to know whether the volume of sales for a given month is related to the amount of advertising the firm does that month. Educators are interested in determining whether the number of hours a student studies is related to the student’s score on a particular exam. Medical researchers are interested in questions such as, Is caffeine related to heart damage? or Is there a relationship between a person’s age and his or her blood pressure? A zoologist may want to know whether the birth weight of a certain animal is related to its life span. These are only a few of the many questions that can be answered by using the techniques of correlation and regression.
analysis. **Correlation** is a statistical method used to determine whether a relationship between variables exists. **Regression** is a statistical method used to describe the nature of the relationship between variables, that is, positive or negative, linear or nonlinear.

The purpose of this chapter is to answer these questions statistically:

1. Are two or more variables related?
2. If so, what is the strength of the relationship?
3. What type of relationship exists?
4. What kind of predictions can be made from the relationship?

To answer the first two questions, statisticians use a numerical measure to determine whether two or more variables are related and to determine the strength of the relationship between or among the variables. This measure is called a **correlation coefficient**. For example, there are many variables that contribute to heart disease, among them lack of exercise, smoking, heredity, age, stress, and diet. Of these variables, some are more important than others; therefore, a physician who wants to help a patient must know which factors are most important.

To answer the third question, one must ascertain what type of relationship exists. There are two types of relationships: simple and multiple. In a **simple relationship**, there are only two variables under study. For example, a manager may wish to see whether the number of years the salespeople have been working for the company has anything to do with the amount of sales they make. This type of study involves a simple relationship, since there are only two variables—years of experience and amount of sales.

In **multiple relationships**, many variables are under study. For example, an educator may wish to investigate the relationship between a student’s success in college and factors such as the number of hours devoted to studying, the student’s GPA, and the student’s high school background. This type of study involves several variables.

Simple relationships can also be positive or negative. A **positive relationship** exists when both variables increase or decrease at the same time. For instance, a person’s height and weight are related; and the relationship is positive, since the taller a person is, generally, the more the person weighs. In a **negative relationship**, as one variable increases, the other variable decreases, and vice versa. For example, if one measures the strength of people over 60 years of age, one will find that as age increases, strength generally decreases. The word *generally* is used here because there are exceptions.

Finally, the fourth question asks what type of predictions can be made. Predictions are made in all areas and daily. Examples include weather forecasting, stock market analyses, sales predictions, crop predictions, gasoline predictions, and sports predictions. Some predictions are more accurate than others, due to the strength of the relationship. That is, the stronger the relationship is between variables, the more accurate the prediction is.

In simple correlation and regression studies, the researcher collects data on two numerical or quantitative variables to see whether a relationship exists between the variables. For example, if a researcher wishes to see whether there is a relationship between number of hours of study and test scores on an exam, she must select a random sample of students, determine the hours each studied, and obtain their grades on the exam. A table can be made for the data, as shown here.
The two variables for this study are called the independent variable and the dependent variable. The independent variable is the variable in regression that can be controlled or manipulated. In this case, “number of hours of study” is the independent variable and is designated as the $x$ variable. The dependent variable is the variable in regression that cannot be controlled or manipulated. The grade the student received on the exam is the dependent variable, designated as the $y$ variable. The reason for this distinction between the variables is that one assumes that the grade the student earns depends on the number of hours the student studied. Also, one assumes that, to some extent, the student can regulate or control the number of hours he or she studies for the exam.

The determination of the $x$ and $y$ variables is not always clear-cut and is sometimes an arbitrary decision. For example, if a researcher studies the effects of age on a person’s blood pressure, the researcher can generally assume that age affects blood pressure. Hence, the variable age can be called the independent variable and the variable blood pressure can be called the dependent variable. On the other hand, if a researcher is studying the attitudes of husbands on a certain issue and the attitudes of their wives on the same issue, it is difficult to say which variable is the independent variable and which is the dependent variable. In this study, the researcher can arbitrarily designate the variables as independent and dependent.

The independent and dependent variables can be plotted on a graph called a scatter plot. The independent variable $x$ is plotted on the horizontal axis, and the dependent variable $y$ is plotted on the vertical axis.

A scatter plot is a graph of the ordered pairs $(x, y)$ of numbers consisting of the independent variable $x$ and the dependent variable $y$.

The scatter plot is a visual way to describe the nature of the relationship between the independent and dependent variables. The scales of the variables can be different, and the coordinates of the axes are determined by the smallest and largest data values of the variables.

The procedure for drawing a scatter plot is shown in Examples 10–1 through 10–3.
Solution

**STEP 1** Draw and label the $x$ and $y$ axes.

**STEP 2** Plot each point on the graph, as shown in Figure 10–1.

---

**Example 10–2**

Construct a scatter plot for the data obtained in a study on the number of absences and the final grades of seven randomly selected students from a statistics class. The data are shown here.

<table>
<thead>
<tr>
<th>Student</th>
<th>Number of absences $x$</th>
<th>Final grade $y$ (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>6</td>
<td>82</td>
</tr>
<tr>
<td>B</td>
<td>2</td>
<td>86</td>
</tr>
<tr>
<td>C</td>
<td>15</td>
<td>43</td>
</tr>
<tr>
<td>D</td>
<td>9</td>
<td>74</td>
</tr>
<tr>
<td>E</td>
<td>12</td>
<td>58</td>
</tr>
<tr>
<td>F</td>
<td>5</td>
<td>90</td>
</tr>
<tr>
<td>G</td>
<td>8</td>
<td>78</td>
</tr>
</tbody>
</table>

**Solution**

**STEP 1** Draw and label the $x$ and $y$ axes.

**STEP 2** Plot each point on the graph, as shown in Figure 10–2.
Construct a scatter plot for the data obtained in a study on the number of hours that nine people exercise each week and the amount of milk (in ounces) each person consumes per week. The data are shown.

<table>
<thead>
<tr>
<th>Subject</th>
<th>Hours x</th>
<th>Amount y</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>3</td>
<td>48</td>
</tr>
<tr>
<td>B</td>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>C</td>
<td>2</td>
<td>32</td>
</tr>
<tr>
<td>D</td>
<td>5</td>
<td>64</td>
</tr>
<tr>
<td>E</td>
<td>8</td>
<td>10</td>
</tr>
<tr>
<td>F</td>
<td>5</td>
<td>32</td>
</tr>
<tr>
<td>G</td>
<td>10</td>
<td>56</td>
</tr>
<tr>
<td>H</td>
<td>2</td>
<td>72</td>
</tr>
<tr>
<td>I</td>
<td>1</td>
<td>48</td>
</tr>
</tbody>
</table>

**Solution**

**STEP 1**  Draw and label the \( x \) and \( y \) axes.

**STEP 2**  Plot each point on the graph, as shown in Figure 10–3.

After the plot is drawn, it should be analyzed to determine which type of relationship, if any, exists. For example, the plot shown in Figure 10–1 suggests a positive relationship, since as a person’s age increases, blood pressure tends to increase also. The plot of the data shown in Figure 10–2 suggests a negative relationship, since as the number of absences increases, the final grade decreases. Finally, the plot of the data shown in Figure 10–3 shows no specific type of relationship, since no pattern is discernible.

Note that the data shown in Figures 10–1 and 10–2 also suggest a linear relationship, since the points seem to fit a straight line, although not perfectly. Sometimes a scatter plot, such as the one in Figure 10–4, will show a curvilinear relationship between the data. In this situation, the methods shown in this section and in Section 10–3 cannot be used. Methods for curvilinear relationships are beyond the scope of this book.
As stated in Section 10–1, statisticians use a measure called the correlation coefficient to determine the strength of the relationship between two variables. There are several types of correlation coefficients. The one explained in this section is called the Pearson product moment correlation coefficient (PPMC), named after statistician Karl Pearson, who pioneered the research in this area.

The correlation coefficient computed from the sample data measures the strength and direction of a linear relationship between two variables. The symbol for the sample correlation coefficient is \( r \). The symbol for the population correlation coefficient is \( \rho \) (Greek letter rho).

As stated in Section 10–1, statisticians use a measure called the correlation coefficient to determine the strength of the relationship between two variables. There are several types of correlation coefficients. The one explained in this section is called the Pearson product moment correlation coefficient (PPMC), named after statistician Karl Pearson, who pioneered the research in this area.

The range of the correlation coefficient is from \(-1\) to \(+1\). If there is a strong positive linear relationship between the variables, the value of \( r \) will be close to \(+1\). If there is a strong negative linear relationship between the variables, the value of \( r \) will be close to \(-1\). When there is no linear relationship between the variables or only a weak relationship, the value of \( r \) will be close to 0. See Figure 10–5.

There are several ways to compute the value of the correlation coefficient. One method is to use the formula shown here.

**Formula for the Correlation Coefficient \( r \)**

\[
r = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{\sqrt{[n(\Sigma x^2) - (\Sigma x)^2][n(\Sigma y^2) - (\Sigma y)^2]}}
\]

where \( n \) is the number of data pairs.
Rounding Rule for the Correlation Coefficient
Round the value of \( r \) to three decimal places.

The formula looks somewhat complicated, but using a table to compute the values, as shown in Example 10-4, makes it somewhat easier to determine the value of \( r \).

Example 10-4
Compute the value of the correlation coefficient for the data obtained in the study of age and blood pressure given in Example 10-1.

**Solution**

**STEP 1** Make a table, as shown here.

<table>
<thead>
<tr>
<th>Subject</th>
<th>Age ( x )</th>
<th>Pressure ( y )</th>
<th>( xy )</th>
<th>( x^2 )</th>
<th>( y^2 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>43</td>
<td>128</td>
<td>5,504</td>
<td>1,849</td>
<td>16,384</td>
</tr>
<tr>
<td>B</td>
<td>48</td>
<td>120</td>
<td>5,760</td>
<td>2,304</td>
<td>14,400</td>
</tr>
<tr>
<td>C</td>
<td>56</td>
<td>135</td>
<td>7,560</td>
<td>3,136</td>
<td>18,225</td>
</tr>
<tr>
<td>D</td>
<td>61</td>
<td>143</td>
<td>8,723</td>
<td>3,721</td>
<td>20,449</td>
</tr>
<tr>
<td>E</td>
<td>67</td>
<td>141</td>
<td>9,447</td>
<td>4,489</td>
<td>19,881</td>
</tr>
<tr>
<td>F</td>
<td>70</td>
<td>152</td>
<td>10,640</td>
<td>4,900</td>
<td>23,104</td>
</tr>
</tbody>
</table>

\[ \Sigma x = 345 \quad \Sigma y = 819 \quad \Sigma xy = 47,634 \quad \Sigma x^2 = 20,399 \quad \Sigma y^2 = 112,443 \]

**STEP 2** Find the values of \( xy, x^2, \) and \( y^2 \) and place these values in the corresponding columns of the table.

The completed table is shown.

<table>
<thead>
<tr>
<th>Subject</th>
<th>Age ( x )</th>
<th>Pressure ( y )</th>
<th>( xy )</th>
<th>( x^2 )</th>
<th>( y^2 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>43</td>
<td>128</td>
<td>5,504</td>
<td>1,849</td>
<td>16,384</td>
</tr>
<tr>
<td>B</td>
<td>48</td>
<td>120</td>
<td>5,760</td>
<td>2,304</td>
<td>14,400</td>
</tr>
<tr>
<td>C</td>
<td>56</td>
<td>135</td>
<td>7,560</td>
<td>3,136</td>
<td>18,225</td>
</tr>
<tr>
<td>D</td>
<td>61</td>
<td>143</td>
<td>8,723</td>
<td>3,721</td>
<td>20,449</td>
</tr>
<tr>
<td>E</td>
<td>67</td>
<td>141</td>
<td>9,447</td>
<td>4,489</td>
<td>19,881</td>
</tr>
<tr>
<td>F</td>
<td>70</td>
<td>152</td>
<td>10,640</td>
<td>4,900</td>
<td>23,104</td>
</tr>
</tbody>
</table>

**STEP 3** Substitute in the formula and solve for \( r \).

\[
r = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{\sqrt{n(\Sigma x^2) - (\Sigma x)^2}[n(\Sigma y^2) - (\Sigma y)^2]}
\]

\[
= \frac{(6)(47,634) - (345)(819)}{\sqrt{[(6)(20,399) - (345)^2][(6)(112,443) - (819)^2]}}
\]

\[ = 0.897 \]

The correlation coefficient suggests a strong positive relationship between age and blood pressure.

Example 10-5
Compute the value of the correlation coefficient for the data obtained in the study of the number of absences and the final grade of the seven students in the statistics class given in Example 10-2.

**Solution**

**STEP 1** Make a table.

**STEP 2** Find the values of \( xy, x^2, \) and \( y^2 \) and place these values in the corresponding columns of the table.
Section 10–3 Correlation

<table>
<thead>
<tr>
<th>Student</th>
<th>Number of absences $x$</th>
<th>Final grade $y$ (%)</th>
<th>$xy$</th>
<th>$x^2$</th>
<th>$y^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>6</td>
<td>82</td>
<td>492</td>
<td>36</td>
<td>6,724</td>
</tr>
<tr>
<td>B</td>
<td>2</td>
<td>86</td>
<td>172</td>
<td>4</td>
<td>7,396</td>
</tr>
<tr>
<td>C</td>
<td>15</td>
<td>43</td>
<td>645</td>
<td>225</td>
<td>1,849</td>
</tr>
<tr>
<td>D</td>
<td>9</td>
<td>74</td>
<td>666</td>
<td>81</td>
<td>5,476</td>
</tr>
<tr>
<td>E</td>
<td>12</td>
<td>58</td>
<td>696</td>
<td>144</td>
<td>3,364</td>
</tr>
<tr>
<td>F</td>
<td>5</td>
<td>90</td>
<td>450</td>
<td>25</td>
<td>8,100</td>
</tr>
<tr>
<td>G</td>
<td>8</td>
<td>78</td>
<td>624</td>
<td>64</td>
<td>6,084</td>
</tr>
</tbody>
</table>

\[
\Sigma x = 57 \quad \Sigma y = 511 \quad \Sigma xy = 3745 \quad \Sigma x^2 = 579 \quad \Sigma y^2 = 38,993
\]

**STEP 3** Substitute in the formula and solve for $r$:

\[
r = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{\sqrt{[n(\Sigma x^2) - (\Sigma x)^2][n(\Sigma y^2) - (\Sigma y)^2]}}
\]

\[
= \frac{(7)(3745) - (57)(511)}{\sqrt{[(7)(579) - (57)^2][(7)(38,993) - (511)^2]}} = -0.944
\]

The value of $r$ suggests a strong negative relationship between a student’s final grade and the number of absences a student has. That is, the more absences a student has, the lower is his or her grade.

---

**Example 10–6**

Compute the value of the correlation coefficient for the data given in Example 10–3 for the number of hours a person exercises and the amount of milk a person consumes per week.

**Solution**

**STEP 1** Make a table.

**STEP 2** Find the values of $xy$, $x^2$, and $y^2$ and place these values in the corresponding columns of the table.

<table>
<thead>
<tr>
<th>Subject</th>
<th>Hours $x$</th>
<th>Amount $y$</th>
<th>$xy$</th>
<th>$x^2$</th>
<th>$y^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>3</td>
<td>48</td>
<td>144</td>
<td>9</td>
<td>2,304</td>
</tr>
<tr>
<td>B</td>
<td>0</td>
<td>8</td>
<td>0</td>
<td>0</td>
<td>64</td>
</tr>
<tr>
<td>C</td>
<td>2</td>

<td>64</td>
<td>4</td>
<td>1,024</td>
</tr>
<tr>
<td>D</td>
<td>5</td>
<td>64</td>
<td>320</td>
<td>25</td>
<td>4,096</td>
</tr>
<tr>
<td>E</td>
<td>8</td>
<td>10</td>
<td>80</td>
<td>64</td>
<td>100</td>
</tr>
<tr>
<td>F</td>
<td>5</td>
<td>32</td>
<td>160</td>
<td>25</td>
<td>1,024</td>
</tr>
<tr>
<td>G</td>
<td>10</td>
<td>56</td>
<td>560</td>
<td>100</td>
<td>3,136</td>
</tr>
<tr>
<td>H</td>
<td>2</td>
<td>72</td>
<td>144</td>
<td>4</td>
<td>5,184</td>
</tr>
<tr>
<td>I</td>
<td>1</td>
<td>48</td>
<td>48</td>
<td>1</td>
<td>2,304</td>
</tr>
</tbody>
</table>

\[
\Sigma x = 36 \quad \Sigma y = 370 \quad \Sigma xy = 1520 \quad \Sigma x^2 = 232 \quad \Sigma y^2 = 19,236
\]

**STEP 3** Substitute in the formula and solve for $r$:

\[
r = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{\sqrt{[n(\Sigma x^2) - (\Sigma x)^2][n(\Sigma y^2) - (\Sigma y)^2]}}
\]

\[
= \frac{(9)(1520) - (36)(370)}{\sqrt{[(9)(232) - (36)^2][(9)(19,236) - (370)^2]}} = 0.067
\]

The value of $r$ indicates a very weak positive relationship between the variables.
In Example 10–4, the value of \( r \) was high (close to 1.00); in Example 10–6, the value of \( r \) was much lower (close to 0). This question then arises: When is the value of \( r \) due to chance and when does it suggest a significant linear relationship between the variables? This question will be answered next.

As stated before, the range of the correlation coefficient is between \(-1\) and \(1\). When the value of \( r \) is near \( +1 \) or \(-1\), there is a strong linear relationship. When the value of \( r \) is near 0, the linear relationship is weak or nonexistent. Since the value of \( r \) is computed from data obtained from samples, there are two possibilities when \( r \) is not equal to zero: either the value of \( r \) is high enough to conclude that there is a significant linear relationship between the variables, or the value of \( r \) is due to chance.

To make this decision, one uses a hypothesis-testing procedure. The traditional method is similar to the one used in previous chapters.

**STEP 1** State the hypotheses.

**STEP 2** Find the critical values.

**STEP 3** Compute the test value.

**STEP 4** Make the decision.

**STEP 5** Summarize the results.

The population correlation coefficient is computed from taking all possible \((x, y)\) pairs; it is designated by the Greek letter \( \rho \) (rho). The sample correlation coefficient can then be used as an estimator of \( \rho \) if the following assumptions are valid.

1. The variables \( x \) and \( y \) are linearly related.
2. The variables are random variables.
3. The two variables have a bivariate normal distribution.

This means for any given value of \( x \), the \( y \) variable is normally distributed.

Formally defined, the **population correlation coefficient** \( \rho \) is the correlation computed by using all possible pairs of data values \((x, y)\) taken from a population.

In hypothesis testing, one of these is true:

\[ H_0: \rho = 0 \quad \text{This null hypothesis means that there is no correlation between the } x \text{ and } y \text{ variables in the population.} \]

\[ H_1: \rho \neq 0 \quad \text{This alternative hypothesis means that there is a significant correlation between the variables in the population.} \]

When the null hypothesis is rejected at a specific level, it means that there is a significant difference between the value of \( r \) and 0. When the null hypothesis is not rejected, it means that the value of \( r \) is not significantly different from 0 (zero) and is probably due to chance.

Several methods can be used to test the significance of the correlation coefficient. Three methods will be shown in this section. The first uses the \( t \) test.
Section 10–3  Correlation  503

Historical Notes
A mathematician named Karl Pearson (1857–1936) became interested in Francis Galton’s work and saw that the correlation and regression theory could be applied to other areas besides heredity. Pearson developed the correlation coefficient that bears his name.

Formula for the t Test for the Correlation Coefficient

\[ t = r \sqrt{\frac{n - 2}{1 - r^2}} \]

with degrees of freedom equal to \( n - 2 \).

Although hypothesis tests can be one-tailed, most hypotheses involving the correlation coefficient are two-tailed. Recall that \( \rho \) represents the population correlation coefficient. Also, if there is no linear relationship, the value of the correlation coefficient will be 0. Hence, the hypotheses will be

\[ H_0: \rho = 0 \quad \text{and} \quad H_1: \rho \neq 0 \]

One does not have to identify the claim here, since the question will always be whether there is a significant linear relationship between the variables.

The two-tailed critical values are used. These values are found in Table F in Appendix C. Also, when one is testing the significance of a correlation coefficient, both variables \( x \) and \( y \) must come from normally distributed populations.

Example 10–7

Test the significance of the correlation coefficient found in Example 10–4. Use \( \alpha = 0.05 \) and \( r = 0.897 \).

Solution

**STEP 1**  State the hypotheses.

\[ H_0: \rho = 0 \quad \text{and} \quad H_1: \rho \neq 0 \]

**STEP 2**  Find the critical values. Since \( \alpha = 0.05 \) and there are \( 6 - 2 = 4 \) degrees of freedom, the critical values obtained from Table F are \( \pm 2.776 \), as shown in Figure 10–6.

**STEP 3**  Compute the test value.

\[ t = r \sqrt{\frac{n - 2}{1 - r^2}} = (0.897) \sqrt{\frac{6 - 2}{1 - (0.897)^2}} = 4.059 \]

**STEP 4**  Make the decision. Reject the null hypothesis, since the test value falls in the critical region, as shown in Figure 10–7.
STEP 5 Summarize the results. There is a significant relationship between the variables of age and blood pressure.

The second method that can be used to test the significance of \( r \) is the \( P \)-value method. The method is the same as that shown in Chapters 8 and 9. It uses the following steps.

STEP 1 State the hypotheses.

STEP 2 Find the test value. (In this case, use the \( t \) test.)

STEP 3 Find the \( P \)-value. (In this case, use Table F.)

STEP 4 Make the decision.

STEP 5 Summarize the results.

Referring to Example 10–7, we see that the \( t \) value obtained in step 3 is 4.059 and d.f. = 4. Using Table F with d.f. = 4 and the row “Two tails,” the value 4.059 falls between 3.747 and 4.604; hence, \( 0.01 < P \)-value < 0.02. (The \( P \)-value obtained from a calculator is 0.015.) That is, the \( P \)-value falls between 0.01 and 0.02. The decision then is to reject the null hypothesis since \( P \)-value < 0.05.

The third method of testing the significance of \( r \) is to use Table I in Appendix C. This table shows the values of the correlation coefficient that are significant for a specific \( \alpha \) level and a specific number of degrees of freedom. For example, for 7 degrees of freedom and \( \alpha = 0.05 \), the table gives a critical value of 0.666. Any value of \( r \) greater than +0.666 or less than −0.666 will be significant, and the null hypothesis will be rejected. See Figure 10–8. When Table I is used, one need not compute the \( t \) test value. Table I is for two-tailed tests only.
Using Table I, test the significance of the correlation coefficient \( r = 0.067 \), obtained in Example 10–6, at \( \alpha = 0.01 \).

Solution

\[ H_0: \rho = 0 \quad \text{and} \quad H_1: \rho \neq 0 \]

Since the sample size is 9, there are 7 degrees of freedom. When \( \alpha = 0.01 \) and with 7 degrees of freedom, the value obtained from Table I is 0.798. For a significant relationship, a value of \( r \) greater than +0.798 or less than −0.798 is needed. Since \( r = 0.067 \), the null hypothesis is not rejected. Hence, there is not enough evidence to say that there is a significant linear relationship between the variables. See Figure 10–9.

Researchers must understand the nature of the linear relationship between the independent variable \( x \) and the dependent variable \( y \). When a hypothesis test indicates that a significant linear relationship exists between the variables, researchers must consider the possibilities outlined next.

Possible Relationships Between Variables

When the null hypothesis has been rejected for a specific \( \alpha \) value, any of the following five possibilities can exist.

1. There is a direct cause-and-effect relationship between the variables. That is, \( x \) causes \( y \).
   For example, water causes plants to grow, poison causes death, and heat causes ice to melt.

(continued)
Chapter 10  Correlation and Regression

Exercises 10–3

1. What is meant by the statement that two variables are related?

2. How is a linear relationship between two variables measured in statistics? Explain.

3. What is the symbol for the sample correlation coefficient? The population correlation coefficient?

4. What is the range of values for the correlation coefficient?

5. What is meant when the relationship between the two variables is positive? Negative?

6. Give examples of two variables that are positively correlated and two that are negatively correlated.

7. Give an example of a correlation study and identify the independent and dependent variables.

8. What is the diagram of the independent and dependent variables called? Why is drawing this diagram important?

9. What is the name of the correlation coefficient used in this section?

10. What statistical test is used to test the significance of the correlation coefficient?

11. When two variables are correlated, can the researcher be sure that one variable causes the other? Why or why not?
Section 10–3  Correlation  507

In correlation and regression studies, it is difficult to control all variables. This study shows some of the consequences when researchers overlook certain aspects. Suggest ways that the extraneous variables might be controlled in future studies.

Coffee Not Disease Culprit, Study Says

NEW YORK (AP)—Two new studies suggest that coffee drinking, even up to 5 1/2 cups per day, does not increase the risk of heart disease, and other studies that claim to have found increased risks might have missed the true culprits, a researcher says.

“It might not be the coffee cup in one hand, it might be the cigarette or coffee roll in the other,” said Dr. Peter W.F. Wilson, the author of one of the new studies.

He noted in a telephone interview Thursday that many coffee drinkers, particularly heavy coffee drinkers, are smokers. And one of the new studies found that coffee drinkers had excess fat in their diets.

The findings of the new studies conflict sharply with a study reported in November 1985 by Johns Hopkins University scientists in Baltimore.

The Hopkins scientists found that coffee drinkers who consumed five or more cups of coffee per day had three times the heart-disease risk of non-coffee drinkers.

The reason for the discrepancy appears to be that many of the coffee drinkers in the Hopkins study also smoked—and it was the smoking that increased their heart-disease risk, said Wilson.

Wilson, director of laboratories for the Framingham Heart Study in Framingham, Mass., said Thursday at a conference sponsored by the American Heart Association in Charleston, S.C., that he had examined the coffee intake of 3,937 participants in the Framingham study during 1956–66 and an additional 2,277 during the years 1972–1982.

In contrast to the subjects in the Hopkins study, most of these coffee drinkers consumed two or three cups per day, Wilson said. Only 10 percent drank six or more cups per day.

He then looked at blood cholesterol levels and heart and blood vessel disease in the two groups. “We ran these analyses for coronary heart disease, heart attack, sudden death and stroke and in absolutely every analysis, we found no link with coffee,” Wilson said.

He found that coffee consumption was linked to a significant decrease in total blood cholesterol in men, and to a moderate increase in total cholesterol in women.

For Exercises 12 through 27, perform the following steps.

a. Draw the scatter plot for the variables.
b. Compute the value of the correlation coefficient.
c. State the hypotheses.
d. Test the significance of the correlation coefficient at \( \alpha = 0.05 \), using Table I.
e. Give a brief explanation of the type of relationship.

12. A manager wishes to find out whether there is a relationship between the number of radio ads aired per week and the amount of sales (in thousands of dollars) of a product. The data for the sample are shown. (The information in this exercise will be used for Exercises 12 and 36 in Section 10–4.)

27. A study was conducted at a large hospital to
determine whether there was a relationship between the
number of years that nurses were employed and the number
of nurses who voluntarily resign. The results are shown. (The
information in this exercise will be used for Exercise 28 of
this section and Exercise 27 of Section 10–4.)

Years employed $x$ | 5 | 6 | 3 | 7 | 8 | 2

Resignations $y$ | 7 | 4 | 7 | 1 | 2 | 8

Extending the Concepts

28. One of the formulas for computing $r$ is

$$r = \frac{\sum(x - \bar{x})(y - \bar{y})}{\sqrt{\sum(x - \bar{x})^2 \sum(y - \bar{y})^2}}$$

Using the data in Exercise 27, compute $r$ with this formula.
Compare the results.

29. Compute $r$ for the data set shown. Explain the
reason for this value of $r$. Now, interchange the values
of $x$ and $y$ and compute $r$ again. Compare this value with
the previous one. Explain the results of the comparison.

30. Compute $r$ for the following data and test the
hypothesis $H_0: \rho = 0$. Draw the scatter plot; then
explain the results.

Students at public graduate schools of law are shown here.
Is there a relationship between the variables? (The
information in this exercise will be used in Exercise 26 in
Section 10–4.)

Median grant $x$ | 1500 | 5500 | 1040 | 3508 | 3823

Avg. indebt. $y$ | 46,500 | 42,332 | 60,000

Source: *U.S. News and World Report Best Graduate Schools.*

In studying relationships between two variables, collect the data and then construct a
scatter plot. The purpose of the scatter plot, as indicated previously, is to determine the
type of the relationship. The possibilities include a positive linear relationship, a nega-
tive linear relationship, a curvilinear relationship, or no discernible relationship. After
the scatter plot is drawn, the next steps are to compute the value of the correlation co-
efficient and to test the significance of the relationship. If the value of the correlation co-
efficient is significant, the next step is to determine the equation of the *regression line,*
which is the data’s line of best fit. (Note: Determining the regression line when $r$ is not
significant and then making predictions using the regression line are meaningless.) The
purpose of the regression line is to enable the researcher to see the trend and make pre-
dictions on the basis of the data.

**Figure 10–10** shows a scatter plot for the data of two variables. It shows that several
lines can be drawn on the graph near the points. Given a scatter plot, one must be able
to draw the *line of best fit.* *Best fit* means that the sum of the squares of the vertical dis-
tances from each point to the line is at a minimum. The reason one needs a line of best

---

**Section 10–4  Regression**

**Objective 4.** Compute the
equation of the regression line.

**Line of Best Fit**
fit is that the values of $y$ will be predicted from the values of $x$; hence, the closer the points are to the line, the better the fit and the prediction will be. See Figure 10–11.

Figure 10–12 shows the relationship between the values of the correlation coefficient and the variability of the scores about the regression line. The closer the points fit the regression line, the higher the absolute value of $r$ and the closer it will be to $1$ or $-1$. When all the points fall exactly on the line, $r$ will equal $1$ or $-1$, and this indicates a perfect linear relationship between the variables. Figure 10–12(a) shows $r$ as positive and approximately equal to $0.50$; Figure 10–12(b) shows $r$ approximately equal to $0.90$; and Figure 10–12(c) shows $r$ equal to $1$. For positive values of $r$, the line slopes upward from left to right.

Figure 10–12(d) shows $r$ as negative and approximately equal to $-0.50$; Figure 10–12(e) shows $r$ approximately equal to $-0.90$; and Figure 10–12(f) shows $r$ equal to $-1$. For negative values of $r$, the line slopes downward from left to right.
In algebra, the equation of a line is usually given as \( y = mx + b \), where \( m \) is the slope of the line and \( b \) is the \( y \) intercept. (Students who need an algebraic review of the properties of a line should refer to Appendix A, Section A–3, before studying this section.) In statistics, the equation of the regression line is written as \( y' = a + bx \), where \( a \) is the \( y' \) intercept and \( b \) is the slope of the line. See Figure 10–13.

There are several methods for finding the equation of the regression line. Two formulas are given here. These formulas use the same values that are used in computing the value of the correlation coefficient. The mathematical development of these formulas is beyond the scope of this book.
Historical Notes

In 1795, Adrien Marie Legendre (1752–1833) measured the meridian arc on the earth's surface from Barcelona, Spain, to Dunkirk, England. This measure was used as the basis for the measure of the meter. Legendre developed the least-squares method around the year 1805.

Formulas for the Regression Line \( y' = a + bx \)

\[
a = \frac{(\sum y)(\sum x^2) - (\sum x)(\sum xy)}{n(\sum x^2) - (\sum x)^2}
\]

\[
b = \frac{n(\sum xy) - (\sum x)(\sum y)}{n(\sum x^2) - (\sum x)^2}
\]

where \( a \) is the \( y' \) intercept and \( b \) is the slope of the line.

Rounding Rule for the Intercept and Slope

Round the values of \( a \) and \( b \) to three decimal places.

Example 10–9

Find the equation of the regression line for the data in Example 10–4, and graph the line on the scatter plot of the data.

Solution

The values needed for the equation are \( n = 6, \sum x = 345, \sum y = 819, \sum xy = 47,634, \) and \( \sum x^2 = 20,399. \) Substituting in the formulas, one gets

\[
a = \frac{(\sum y)(\sum x^2) - (\sum x)(\sum xy)}{n(\sum x^2) - (\sum x)^2} = \frac{(819)(20,399) - (345)(47,634)}{(6)(20,399) - (345)^2} = 81.048
\]

\[
b = \frac{n(\sum xy) - (\sum x)(\sum y)}{n(\sum x^2) - (\sum x)^2} = \frac{(6)(47,634) - (345)(819)}{(6)(20,399) - (345)^2} = 0.964
\]

Hence, the equation of the regression line \( y' = a + bx \) is

\[ y' = 81.048 + 0.964x \]

The graph of the line is shown in Figure 10–14.

Figure 10–14

Regression Line for Example 10–9

Note: When one is drawing the scatter plot and the regression line, it is sometimes desirable to \textit{truncate} the graph (see Chapter 2). The motive is to show the line drawn in the range of the independent and dependent variables. For example, the regression line in Figure 10–14 is drawn between the \( x \) values of approximately 43 and 82 and the \( y' \) values of approximately 120 and 152. The range of the \( x \) values in the original data...
shown in Example 10–4 is $70 - 43 = 27$, and the range of the $y'$ values is $152 - 120 = 32$. Notice that the $x$ axis has been truncated; the distance between 0 and 40 is not shown in the proper scale compared to the distance between 40 and 50, 50 and 60, etc. The $y'$ axis has been similarly truncated.

The important thing to remember is that when the $x$ axis and sometimes the $y'$ axis have been truncated, do not use the $y'$ intercept value $a$ to graph the line. To be on the safe side when graphing the regression line, use a value for $x$ selected from the range of $x$ values.

Example 10–10

Find the equation of the regression line for the data in Example 10–5, and graph the line on the scatter plot.

Solution

The values needed for the equation are $n = 7$, $\Sigma x = 57$, $\Sigma y = 511$, $\Sigma xy = 3745$, and $\Sigma x^2 = 579$. Substituting in the formulas, one gets

$$a = \frac{(\Sigma y)(\Sigma x^2) - (\Sigma x)(\Sigma xy)}{n(\Sigma x^2) - (\Sigma x)^2} = \frac{(511)(579) - (57)(3745)}{(7)(579) - (57)^2} = 102.493$$

$$b = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{n(\Sigma x^2) - (\Sigma x)^2} = \frac{(7)(3745) - (57)(511)}{(7)(579) - (57)^2} = -3.622$$

Hence, the equation of the regression line $y' = a + bx$ is

$$y' = 102.493 - 3.622x$$

The graph of the line is shown in Figure 10–15.

The sign of the correlation coefficient and the sign of the slope of the regression line will always be the same. That is, if $r$ is positive, then $b$ will be positive; if $r$ is negative, then $b$ will be negative. The reason is that the numerators of the formulas are the same and determine the signs of $r$ and $b$, and the denominators are always positive. The
regression line will always pass through the point whose x coordinate is the mean of the x values and whose y coordinate is the mean of the y values, that is \((\bar{x}, \bar{y})\).

The regression line can be used to make predictions for the dependent variable. The method for making predictions is shown in Example 10–11.

**Example 10–11**

Using the equation of the regression line found in Example 10–9, predict the blood pressure for a person who is 50 years old.

**Solution**

Substituting 50 for \(x\) in the regression line \(y' = 81.048 + 0.964x\) gives

\[
y' = 81.048 + (0.964)(50) = 129.248 \text{ (rounded to 129)}
\]

In other words, the predicted systolic blood pressure for a 50-year-old person is 129.

The value obtained in Example 10–11 is a point prediction, and with point predictions, no degree of accuracy or confidence can be determined. More information on prediction is given in Section 10–5.

The magnitude of the change in one variable when the other variable changes exactly 1 unit is called a **marginal change**. The value of slope \(b\) of the regression line equation represents the marginal change. For example, the slope of the regression line equation in Example 10–9 is 0.964. This means that for each increase of 1 year, the value of \(y\) (blood pressure reading) changes by 0.964 unit. In other words, for each year a person ages, her or his blood pressure rises about 1 unit.

*When \(r\) is not significantly different from 0, the best predictor of \(y\) is the mean of the data values of \(y\).* For valid predictions, the value of the correlation coefficient must be significant. Also, two other assumptions must be met.

### Assumptions for Valid Predictions in Regression

1. For any specific value of the independent variable \(x\), the value of the dependent variable \(y\) must be normally distributed about the regression line. See Figure 10–16(a).
2. The standard deviation of each of the dependent variables must be the same for each value of the independent variable. See Figure 10–16(b).

**Figure 10–16**

Assumptions for Predictions

(a) Dependent variable \(y\) normally distributed

(b) \(\sigma_1 = \sigma_2 = \cdots = \sigma_n\)
Extrapolation, or making predictions beyond the bounds of the data, must be interpreted cautiously. For example, in 1979, some experts predicted that the United States would run out of oil by the year 2003. This prediction was based on the current consumption and on known oil reserves at that time. However, since then, the automobile industry has produced many new fuel-efficient vehicles. Also, there are many as yet undiscovered oil fields. Finally, science may someday discover a way to run a car on something as unlikely but as common as peanut oil. In addition, the price of a gallon of gasoline was predicted to reach $10 a few years later. Fortunately this has not come to pass. Remember that when predictions are made, they are based on present conditions or on the premise that present trends will continue. This assumption may or may not prove true in the future.

The steps for finding the value of the correlation coefficient and the regression line equation are summarized in this Procedure Table:

**Procedure Table**

**Finding the Correlation Coefficient and the Regression Line Equation**

**STEP 1** Make a table, as shown in step 2.

**STEP 2** Find the values of $xy$, $x^2$, and $y^2$. Place them in the appropriate columns and sum each column.

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
<th>$xy$</th>
<th>$x^2$</th>
<th>$y^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

$\Sigma x = \Sigma y = \Sigma xy = \Sigma x^2 = \Sigma y^2 = \ldots$

**STEP 3** Substitute in the formula to find the value of $r$.

$$r = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{\sqrt{n(\Sigma x^2) - (\Sigma x)^2}[n(\Sigma y^2) - (\Sigma y)^2]}$$

**STEP 4** When $r$ is significant, substitute in the formulas to find the values of $a$ and $b$ for the regression line equation $y' = a + bx$.

$$a = \frac{(\Sigma y)(\Sigma x^2) - (\Sigma x)(\Sigma xy)}{n(\Sigma x^2) - (\Sigma x)^2}$$

$$b = \frac{n(\Sigma xy) - (\Sigma x)(\Sigma y)}{n(\Sigma x^2) - (\Sigma x)^2}$$

A scatter plot should be checked for outliers. An outlier is a point that seems out of place when compared with the other points (see Chapter 3). Some of these points can affect the equation of the regression line. When this happens, the points are called **influential points** or **influential observations**.

When a point on the scatter plot appears to be an outlier, it should be checked to see if it is an influential point. An influential point tends to “pull” the regression line toward the point itself. To check for an influential point, the regression line should be graphed with the point included in the data set. Then a second regression line should be graphed that excludes the point from the data set. If the position of the second line is changed considerably, the point is said to be an influential point. Points that are outliers in the $x$ direction tend to be influential points.

Researchers should use their judgment as to whether to include influential observations in the final analysis of the data. If the researcher feels that the observation is not
necessary, then it should be excluded so that it does not influence the results of the study. However, if the researcher feels that it is necessary, then he or she may want to obtain additional data values whose \( x \) values are near the \( x \) value of the influential point and then include them in the study.

Exercises 10–4

1. What two things should be done before one performs a regression analysis?

2. What are the assumptions for regression analysis?

3. What is the general form for the regression line used in statistics?

4. What is the symbol for the slope? For the \( y \) intercept?

5. What is meant by the line of best fit?

6. When all the points fall on the regression line, what is the value of the correlation coefficient?

7. What is the relationship of the sign of the correlation coefficient and the sign of the slope of the regression line?

8. As the value of the correlation coefficient increases from 0 to 1, or decreases from 0 to \(-1\), how do the points of the scatter plot fit the regression line?

9. How is the value of the correlation coefficient related to the accuracy of the predicted value for a specific value of \( x \)?

10. If the value of \( r \) is not significant, what can be said about the regression line?

11. When the value of \( r \) is not significant, what value should be used to predict \( y \)?

For Exercises 12 through 27, use the same data as for the corresponding exercises in Section 10–3. For each exercise, find the equation of the regression line and find the \( y' \) value for the specified \( x \) value. Remember that no regression should be done when \( r \) is not significant.

12. Number of ads and sales

<table>
<thead>
<tr>
<th>No. of ads ( x )</th>
<th>2</th>
<th>5</th>
<th>8</th>
<th>8</th>
<th>10</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sales ( y ), $</td>
<td>2</td>
<td>4</td>
<td>7</td>
<td>6</td>
<td>9</td>
<td>10</td>
</tr>
</tbody>
</table>

Find \( y' \) when \( x = 7 \) ads.

13. Ages and exercise

<table>
<thead>
<tr>
<th>Age ( x )</th>
<th>18</th>
<th>26</th>
<th>32</th>
<th>38</th>
<th>52</th>
<th>59</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hours ( y )</td>
<td>10</td>
<td>5</td>
<td>2</td>
<td>3</td>
<td>1.5</td>
<td>1</td>
</tr>
</tbody>
</table>

Find \( y' \) when \( x = 35 \) years.

14. Income and meals

<table>
<thead>
<tr>
<th>Income ( x ), $</th>
<th>500</th>
<th>1200</th>
<th>1500</th>
<th>945</th>
<th>850</th>
<th>400</th>
<th>540</th>
</tr>
</thead>
<tbody>
<tr>
<td>Meals ( y )</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>10</td>
<td>9</td>
<td>3</td>
<td>7</td>
</tr>
</tbody>
</table>

Find \( y' \) when \( x = $1100 \).

15. Years and contribution

<table>
<thead>
<tr>
<th>Years ( x )</th>
<th>1</th>
<th>5</th>
<th>3</th>
<th>10</th>
<th>7</th>
<th>6</th>

</table>

Find \( y' \) when \( x = 4 \) years.

### For Exercises 28 through 33, do a complete regression analysis by performing these steps.

1. Draw a scatter plot.
2. Compute the correlation coefficient.
3. State the hypotheses.
4. Test the hypotheses at \( \alpha = 0.05 \). Use Table I.
5. Determine the regression line equation.
6. Plot the regression line on the scatter plot.
7. Summarize the results.

28. These data were obtained for the years 1993 through 1998 and indicate the number of fireworks (in millions) used and the related injuries. Predict the number of injuries if 100 million fireworks are used during a given year.

<table>
<thead>
<tr>
<th>Fireworks in use</th>

<td>Son’s weight y</td>
<td>6.6 8.2 9.2 7.1 8.8 9.3 7.4 8.6</td>
</tr>
</tbody>
</table>

35. A car dealership owner wishes to determine if
there is a relationship between the number of years of
experience a salesperson has and the number of cars sold
per month. The data are given here.

<table>
<thead>
<tr>
<th>Years of experience x</th>
<th>3 9 2 5 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of cars sold per month y</td>
<td>5 14 12 21 8</td>
</tr>
</tbody>
</table>

For Exercises 34 and 35, do a complete regression
analysis and test the significance of $r$ at $\alpha = 0.05$, using
the $P$-value method.

Verify this result by using the data in Exercises 15, 16, and
17 of Sections 10–3 and 10–4.

38. The value of the correlation coefficient can also be
found by using the formula

$$ r = \frac{\overline{x}b - \overline{y}}{s_x s_y} $$

where $s_x$ is the standard deviation of the $x$ value, and $s_y$ is
the standard deviation of the $y$ values. Verify this result for
Exercises 18, 19, and 20 of Section 10–3.

---

**Extending the Concepts**

36. For Exercises 12, 13, and 14 in Section 10–3, find the
mean of the $x$ and $y$ variables. Then substitute the mean of
the $x$ variable into the corresponding regression line
equations found in Exercises 12, 13, and 14 in this section
and find $y'$. Compare the value of $y'$ with $\overline{y}$ for each
exercise. Generalize the results.

37. The $y$ intercept value $a$ can also be found by using the
equation

$$ a = \overline{y} - b\overline{x} $$

**Technology Step by Step**

**MINITAB**

**Create a Scatter Plot**

1. These instructions use Example 10–1. Enter the data into three columns of data. The
subject column is optional (see step 6b).

10–26
2. Name the columns C1 Subject, C2 Age, and C3 Pressure.
3. Select **Graph>Scatterplot**, then select Simple and click [OK].
5. Click [Data View]. The Data Display should be Symbols. If not, click the option box to select it. Click [OK].
6. Click [Labels].
   a) Type **Pressure vs. Age** in the text box for Titles/Footnotes, then type **Your Name** in the box for Subtitle 1.
   b) **Optional:** Click the tab for Data Labels, then click the option to Use labels from column.
   c) Select C1 Subject.
7. Click [OK] twice.

**Calculate the Correlation Coefficient**
8. Select **Stat>Basic Statistics>Correlation.**
9. Double-click C3 Pressure, then double-click C2 Age. The box for Display p-values should be checked.
10. Click [OK]. The correlation coefficient will be displayed in the session window, \( r = 0.897 \) with a \( P \)-value of 0.015.

**Determine the Equation of the Least-Squares Regression Line**
11. Select **Stat>Regression>Regression.**
12. Double-click Pressure in the variable list to select it for the **Response** variable Y.
13. Double-click C2 Age in the variable list to select it for the **Predictors** variable X.
14. Click on [Storage], then check the boxes for **Residuals** and **Fits**.
15. Click [OK] twice.
The session window will contain the regression analysis as shown.

In the worksheet two new columns will be added with the fitted values and residuals. Summary: The scatter plot and correlation coefficient confirm a strong positive linear correlation between pressure and age. The null hypothesis would be rejected at a significance level of 0.015. The equation of the regression equation is Pressure = 81.0 + 0.964 (Age).

Regression Analysis: Pressure versus Age
The regression equation is
Pressure = 81.0 + 0.964 Age

 Predictor Coef SE Coef T P Constant 81.05 13.88 5.84 0.004 Age 0.9644 0.2381 4.05 0.015

R = 5.641 R-Sq = 80.4% R-Sq (adj) = 75.5%

Analysis of Variance
Source DF SS MS F P
Regression 1 522.21 522.21 16.41 0.015
Residual Error 4 127.29 31.82
Total 5 649.50

Correlation and Regression
To graph a scatter plot:
1. Enter the x values in L₁ and the y values in L₂.
2. Make sure the Window values are appropriate. Select an Xmin slightly less than the smallest x data value and an Xmax slightly larger than the largest x data value. Do the same for Ymin and Ymax. Also, you may need to change the Xscl and Yscl values, depending on the data.
3. Press 2nd [STAT PLOT] 1 for Plot 1. The other y functions should be turned off.
4. Move the cursor to On and press ENTER on the Plot 1 menu.
5. Move the cursor to the graphic that looks like a scatter plot next to Type (first graph), and press ENTER. Make sure the X list is L₁, and the Y list is L₂.
6. Press GRAPH.
Example TI10–1

Draw a scatter plot for the data from Example 10–1.

<table>
<thead>
<tr>
<th>x</th>
<th>43</th>
<th>48</th>
<th>56</th>
<th>61</th>
<th>67</th>
<th>70</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>128</td>
<td>120</td>
<td>135</td>
<td>143</td>
<td>141</td>
<td>152</td>
</tr>
</tbody>
</table>

The input and output screens are shown.

To find the equation of the regression line:
1. Press STAT and move the cursor to Calc.
2. Press 8 for LinReg(a+bx) then ENTER. The values for a and b will be displayed.

In order to have the calculator compute and display the correlation coefficient and coefficient of determination as well as the equation of the line, you must set the diagnostics display mode to on. Follow these steps:
1. Press 2nd [CATALOG].
2. Use the arrow keys to scroll down to DiagnosticOn.
3. Press ENTER to copy the command to the home screen.
4. Press ENTER to execute the command.

You will have to do this only once. Diagnostic display mode will remain on until you perform a similar set of steps to turn it off.

Example TI10–2

Find the equation of the regression line for the data in TI10–1, as shown in Example 10–9. The input and output screens are shown.

The equation of the regression line is \( y' = 81.04808549 + 0.964381122x \).

To plot the regression line on the scatter plot:
1. Press Y= and CLEAR to clear any previous equations.
2. Press VARS and then 5 for Statistics.
3. Move the cursor to EQ and press 1 for RegEQ. The line will be in the Y= screen.
4. Press GRAPH.
Example TI10–3

Draw the regression line found in Example TI10–2 on the scatter plot.

The output screens are shown.

To test the significance of \( b \) and \( r \):

1. Press \texttt{STAT} and move the cursor to \texttt{TESTS}.
2. Press \texttt{E (ALPHA SIN)} for \texttt{LinRegTTest}. Make sure the \texttt{Xlist} is \( L_1 \), the \texttt{Ylist} is \( L_2 \), and the \texttt{Freq} is 1.
3. Select the appropriate alternative hypothesis.
4. Move the cursor to \texttt{Calculate} and press \texttt{ENTER}.

Example TI10–4

Test the hypothesis from Examples 10–4 and 10–7, \( H_0: \rho = 0 \) for the data in Example 10–1. Use \( \alpha = 0.05 \).

In this case, the \( t \) test value is 4.050983638. The \( P \)-value is 0.0154631742, which is significant.

There are two other ways to store the equation for the regression line in \( Y_1 \) for graphing.

1. Type \( Y_1 \) after the \texttt{LinReg(a+bx)} command.
2. Type \( Y_1 \) in the \texttt{RegEQ:} spot in the \texttt{LinRegTTest}.

To get \( Y_1 \) do this:
Press \texttt{VARS} for variables, move cursor to \texttt{Y-VARS}, press 1 for Function, press 1 for \( Y_1 \).

---

**Excel Step by Step**

Creating scatter plots in Excel is straightforward when one uses the Chart Wizard.

1. Click on the Chart Wizard icon (it looks like a colorful histogram).
2. Select chart type \( XY \) (Scatter) under the \texttt{Standard Types} tab. Click on \texttt{[Next >]}.
3. Enter the data range, and specify whether the data for each variable are stored in columns (as we have done in our examples) or rows. Click on \texttt{[Next >]}. 

---

**Scatter Plots**

Creating scatter plots in Excel is straightforward when one uses the Chart Wizard.

1. Click on the Chart Wizard icon (it looks like a colorful histogram).
2. Select chart type \( XY \) (Scatter) under the \texttt{Standard Types} tab. Click on \texttt{[Next >]}.
3. Enter the data range, and specify whether the data for each variable are stored in columns (as we have done in our examples) or rows. Click on \texttt{[Next >]}. 

---
4. The next dialog box enables you to set various options for displaying the plot. In most cases, the defaults will be okay. After entering the desired options (note that there are several tabs for this screen), click on [Next >].

5. Use this final dialog box to specify where the chart will be located. Click on [Finish].

**Correlation Coefficient**

The CORREL function returns the correlation coefficient.

1. Enter the data in columns A and B.
2. Select a blank cell, then click on the fx button.
3. Under Function category, select Statistical. From the Function name list, select CORREL.
4. Enter the data range (A1:AN, where N is the number of sample data pairs) for the first variable in Array1. Enter the data range for the second variable in Array2. The correlation coefficient will be displayed in the selected cell.

**Correlation and Regression**

This procedure will allow you to calculate the Pearson product moment correlation coefficient without performing a regression analysis.

1. Enter the data from Example 10–2 in a new worksheet. Enter the seven values for the numbers of absences in column A and the corresponding final grades in column B.
2. Select Tools>Data Analysis>Correlation. Click the icon next to the Input Range box. This will minimize the dialog box. Use the mouse to highlight the data from columns A and B. Once the data are selected, click the icon to restore the box.
3. Make sure that the data are grouped by columns, and select New Worksheet Ply, then click [OK].

This procedure will allow you to conduct a regression analysis and compute the correlation coefficient.

1. Enter the seven values for the number of absences in column A and the corresponding final grades in column B.
2. Select Tools>Data Analysis>Regression.
3. Enter B1:B7 for the Input Y Range, and then enter A1:A7 for the Input X Range.
4. Click [OK].
The previous sections stated that if the correlation coefficient is significant, the equation of the regression line can be determined. Also, for various values of the independent variable \( x \), the corresponding values of the dependent variable \( y \) can be predicted. Several other measures are associated with the correlation and regression techniques. They include the coefficient of determination, the standard error of estimate, and the prediction interval. But before these concepts can be explained, the different types of variation associated with the regression model must be defined.

Consider the following hypothetical regression model.

<table>
<thead>
<tr>
<th>( x )</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>( y )</td>
<td>10</td>
<td>8</td>
<td>12</td>
<td>16</td>
<td>20</td>
</tr>
</tbody>
</table>

The equation of the regression line is \( y' = 4.8 + 2.8x \), and \( r = 0.919 \). The sample \( y \) values are 10, 8, 12, 16, and 20. The predicted values, designated by \( y' \), for each \( x \) can be found by substituting each \( x \) value into the regression equation and finding \( y' \). For example, when \( x = 1 \),

\[
y' = 4.8 + 2.8(1) = 7.6
\]

Now, for each \( x \), there is an observed \( y \) value and a predicted \( y' \) value, for example, when \( x = 1 \), \( y = 10 \), and \( y' = 7.6 \). Recall that the closer the observed values are to the predicted values, the better the fit is and the closer \( r \) is to \(+1\) or \(-1\).

The total variation \( \Sigma (y - \bar{y})^2 \) is the sum of the squares of the vertical distances each point is from the mean. The total variation can be divided into two parts: that which is attributed to the relationship of \( x \) and \( y \) and that which is due to chance. The variation obtained from the relationship (i.e., from the predicted \( y' \) values) is \( \Sigma (y' - \bar{y})^2 \) and is called the explained variation. Most of the variations can be explained by the relationship. The closer the value \( r \) is to \(+1\) or \(-1\), the better the points fit the line, and the closer \( \Sigma (y' - \bar{y})^2 \) is to \( \Sigma (y - \bar{y})^2 \). In fact, if all points fall on the regression line, \( \Sigma (y' - \bar{y})^2 \) will equal \( \Sigma (y - \bar{y})^2 \), since \( y' \) would be equal to \( y \) in each case.

On the other hand, the variation due to chance, found by \( \Sigma (y - y')^2 \), is called the unexplained variation. This variation cannot be attributed to the relationship. When the unexplained variation is small, the value of \( r \) is close to \(+1\) or \(-1\). If all points fall on the regression line, the unexplained variation \( \Sigma (y - y')^2 \) will be 0. Hence, the total variation is equal to the sum of the explained variation and the unexplained variation. That is,

\[
\Sigma (y - \bar{y})^2 = \Sigma (y' - \bar{y})^2 + \Sigma (y - y')^2
\]

These values are shown in Figure 10–17. For a single point, the differences are called deviations. For the hypothetical regression model given earlier, for \( x = 1 \) and \( y = 10 \), one gets \( y' = 7.6 \) and \( \bar{y} = 13.2 \).

The procedure for finding the three types of variation is illustrated next.

**STEP 1** Find the predicted \( y' \) values.

- For \( x = 1 \) \( y' = 4.8 + 2.8(1) = 7.6 \)
- For \( x = 2 \) \( y' = 4.8 + 2.8(2) = 10.4 \)
- For \( x = 3 \) \( y' = 4.8 + 2.8(3) = 13.2 \)
- For \( x = 4 \) \( y' = 4.8 + 2.8(4) = 16.0 \)
- For \( x = 5 \) \( y' = 4.8 + 2.8(5) = 18.8 \)
Hence, the values for this example are as follows:

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>y'</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
<td>7.6</td>
</tr>
<tr>
<td>2</td>
<td>8</td>
<td>10.4</td>
</tr>
<tr>
<td>3</td>
<td>12</td>
<td>13.2</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>16.0</td>
</tr>
<tr>
<td>5</td>
<td>20</td>
<td>18.8</td>
</tr>
</tbody>
</table>

**STEP 2** Find the mean of the \( y \) values.

\[
\bar{y} = \frac{10 + 8 + 12 + 16 + 20}{5} = 13.2
\]

**STEP 3** Find the total variation \( \Sigma (y - \bar{y})^2 \).

\[
\begin{align*}
(10 - 13.2)^2 &= 10.24 \\
(8 - 13.2)^2 &= 27.04 \\
(12 - 13.2)^2 &= 1.44 \\
(16 - 13.2)^2 &= 7.84 \\
(20 - 13.2)^2 &= 46.24 \\
\Sigma (y - \bar{y})^2 &= 92.8
\end{align*}
\]

**STEP 4** Find the explained variation \( \Sigma (y' - \bar{y})^2 \).

\[
\begin{align*}
(7.6 - 13.2)^2 &= 31.36 \\
(10.4 - 13.2)^2 &= 7.84 \\
(13.2 - 13.2)^2 &= 0.00 \\
(16 - 13.2)^2 &= 7.84 \\
(18.8 - 13.2)^2 &= 31.36 \\
\Sigma (y' - \bar{y})^2 &= 78.4
\end{align*}
\]

**STEP 5** Find the unexplained variation \( \Sigma (y - y')^2 \).

\[
\begin{align*}
\Sigma (y - y')^2 &= 92.8 - 78.4 = 14.4
\end{align*}
\]
Chapter 10  Correlation and Regression

Coefficient of Determination

Objective 5. Compute the coefficient of determination.

Historical Note
Karl Pearson recommended in 1897 that the French government close all its casinos and turn the gambling devices over to the academic community to use in the study of probability.

\[
\begin{align*}
(10 - 7.6)^2 &= 5.76 \\
(8 - 10.4)^2 &= 5.76 \\
(12 - 13.2)^2 &= 1.44 \\
(16 - 16)^2 &= 0.00 \\
(20 - 18.8)^2 &= 1.44 \\
\sum (y - y')^2 &= 14.4
\end{align*}
\]

Notice that

\[
\text{Total variation} = \text{Explained variation} + \text{Unexplained variation}
\]

\[
92.8 = 78.4 + 14.4
\]

Note: The values \(y - y')\) are called residuals. A residual is the difference between the actual value of \(y\) and the predicted value \(y'\) for a given \(x\) value. The mean of the residuals is always zero. As stated previously, the regression line determined by the formulas in Section 10–4 is the line that best fits the points of the scatter plot. The sum of the squares of the residuals computed by using the regression line is the smallest possible value. For this reason, a regression line is also called a least-squares line.

The coefficient of determination is the ratio of the explained variation to the total variation and is denoted by \(r^2\). That is,

\[
r^2 = \frac{\text{explained variation}}{\text{total variation}}
\]

For the example, \(r^2 = 78.4/92.8 = 0.845\). The term \(r^2\) is usually expressed as a percentage. So in this case, 84.5% of the total variation is explained by the regression line using the independent variable.

Another way to arrive at the value for \(r^2\) is to square the correlation coefficient. In this case, \(r = 0.919\) and \(r^2 = 0.845\), which is the same value found by using the variation ratio.

The coefficient of determination is a measure of the variation of the dependent variable that is explained by the regression line and the independent variable. The symbol for the coefficient of determination is \(r^2\).

Of course, it is usually easier to find the coefficient of determination by squaring \(r\) and converting it to a percentage. Therefore, if \(r = 0.90\), then \(r^2 = 0.81\), which is equivalent to 81%. This result means that 81% of the variation in the dependent variable is accounted for by the variations in the independent variable. The rest of the variation, 0.19, or 19%, is unexplained. This value is called the coefficient of nondetermination and is found by subtracting the coefficient of determination from 1. As the value of \(r\) approaches 0, \(r^2\) decreases more rapidly. For example, if \(r = 0.6\), then \(r^2 = 0.36\), which means that only 36% of the variation in the dependent variable can be attributed to the variation in the independent variable.

Coefficient of Nondetermination

\[
1.00 - r^2
\]
When a $y'$ value is predicted for a specific $x$ value, the prediction is a point prediction. However, a prediction interval about the $y'$ value can be constructed, just as a confidence interval was constructed for an estimate of the population mean. The prediction interval uses a statistic called the *standard error of the estimate*.

The **standard error of the estimate**, denoted by $s_{est}$, is the standard deviation of the observed $y$ values about the predicted $y'$ values. The formula for the standard error of estimate is

$$s_{est} = \sqrt{\frac{\sum (y - y')^2}{n - 2}}$$

The standard error of the estimate is similar to the standard deviation, but the mean is not used. As can be seen from the formula, the standard error of the estimate is the square root of the unexplained variation—that is, the variation due to the difference of the observed values and the expected values—divided by $n - 2$. So the closer the observed values are to the predicted values, the smaller the standard error of the estimate will be.

Example 10–12 shows how to compute the standard error of the estimate.

**Example 10–12**

A researcher collects the following data and determines that there is a significant relationship between the age of a copy machine and its monthly maintenance cost. The regression equation is $y' = 55.57 + 8.13x$. Find the standard error of the estimate.

<table>
<thead>
<tr>
<th>Machine</th>
<th>Age $x$ (years)</th>
<th>Monthly cost $y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
<td>$62</td>
</tr>
<tr>
<td>B</td>
<td>2</td>
<td>78</td>
</tr>
<tr>
<td>C</td>
<td>3</td>
<td>70</td>
</tr>
<tr>
<td>D</td>
<td>4</td>
<td>90</td>
</tr>
<tr>
<td>E</td>
<td>4</td>
<td>93</td>
</tr>
<tr>
<td>F</td>
<td>6</td>
<td>103</td>
</tr>
</tbody>
</table>

**Solution**

**STEP 1** Make a table, as shown.

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
<th>$y'$</th>
<th>$y - y'$</th>
<th>$(y - y')^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>62</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>78</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>70</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>90</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>93</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>103</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**STEP 2** Using the regression line equation $y' = 55.57 + 8.13x$, compute the predicted values $y'$ for each $x$ and place the results in the column labeled $y'$.

- $x = 1 \quad y' = 55.57 + (8.13)(1) = 63.70$
- $x = 2 \quad y' = 55.57 + (8.13)(2) = 71.83$
- $x = 3 \quad y' = 55.57 + (8.13)(3) = 79.96$
- $x = 4 \quad y' = 55.57 + (8.13)(4) = 88.09$
- $x = 6 \quad y' = 55.57 + (8.13)(6) = 104.35$
**STEP 3** For each y, subtract $y'$ and place the answer in the column labeled $y - y'$.

- $62 - 63.70 = -1.70$
- $90 - 88.09 = 1.91$
- $78 - 71.83 = 6.17$
- $93 - 88.09 = 4.91$
- $70 - 79.96 = -9.96$
- $103 - 104.35 = -1.35$

**STEP 4** Square the numbers found in step 3 and place the squares in the column labeled $(y - y')^2$.

**STEP 5** Find the sum of the numbers in the last column. The completed table is shown.

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>$y'$</th>
<th>$y - y'$</th>
<th>$(y - y')^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>62</td>
<td>63.70</td>
<td>-1.70</td>
<td>2.89</td>
</tr>
<tr>
<td>2</td>
<td>78</td>
<td>71.83</td>
<td>6.17</td>
<td>38.0689</td>
</tr>
<tr>
<td>4</td>
<td>90</td>
<td>88.09</td>
<td>1.91</td>
<td>3.6481</td>
</tr>
<tr>
<td>4</td>
<td>93</td>
<td>88.09</td>
<td>4.91</td>
<td>24.1081</td>
</tr>
<tr>
<td>6</td>
<td>103</td>
<td>104.35</td>
<td>-1.35</td>
<td>1.8225</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>169.7392</td>
</tr>
</tbody>
</table>

**STEP 6** Substitute in the formula and find $s_{est}$.

$$s_{est} = \sqrt{\frac{\sum (y - y')^2}{n - 2}} = \sqrt{\frac{169.7392}{6 - 2}} = 6.51$$

In this case, the standard deviation of observed values about the predicted values is 6.51.

The standard error of the estimate can also be found by using the formula

$$s_{est} = \sqrt{\frac{\sum y^2 - a \sum y - b \sum xy}{n - 2}}$$

**Example 10–13** Find the standard error of the estimate for the data for Example 10–12 by using the preceding formula. The equation of the regression line is $y' = 55.57 + 8.13x$.

**Solution**

**STEP 1** Make a table.

**STEP 2** Find the product of x and y values, and place the results in the third column.

**STEP 3** Square the y values, and place the results in the fourth column.

**STEP 4** Find the sums of the second, third, and fourth columns. The completed table is shown here.

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>xy</th>
<th>$y^2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>62</td>
<td>62</td>
<td>3,844</td>
</tr>
<tr>
<td>2</td>
<td>78</td>
<td>156</td>
<td>6,084</td>
</tr>
<tr>
<td>3</td>
<td>70</td>
<td>210</td>
<td>4,900</td>
</tr>
<tr>
<td>4</td>
<td>90</td>
<td>360</td>
<td>8,100</td>
</tr>
<tr>
<td>4</td>
<td>93</td>
<td>372</td>
<td>8,649</td>
</tr>
<tr>
<td>6</td>
<td>103</td>
<td>618</td>
<td>10,609</td>
</tr>
</tbody>
</table>

$\sum y = 496$  $\sum xy = 1778$  $\sum y^2 = 42,186$
**STEP 5** From the regression equation \( y' = 55.57 + 8.13x \), \( a = 55.57 \) and \( b = 8.13 \).

**STEP 6** Substitute in the formula and solve for \( s_{est} \).

\[
s_{est} = \sqrt{\frac{\sum y^2 - a \sum y - b \sum xy}{n - 2}}
\]

\[
= \sqrt{\frac{42,186 - (55.57)(496) - (8.13)(1778)}{6 - 2}} = 6.48
\]

This value is close to the value found in Example 10–12. The difference is due to rounding.

---

**Prediction Interval**

**Objective 7.** Find a prediction interval.

The standard error of estimate can be used for constructing a **prediction interval** (similar to a confidence interval) about a \( y' \) value.

When a specific value \( x \) is substituted into the regression equation, one gets \( y' \), which is a point estimate for \( y \). For example, if the regression line equation for the age of a machine and the monthly maintenance cost is \( y' = 55.57 + 8.13x \) (Example 10–12), then the predicted maintenance cost for a 3-year-old machine would be \( y' = 55.57 + 8.13(3) \), or $79.96. Since this is a point estimate, one has no idea how accurate it is. But one can construct a prediction interval about the estimate. By selecting an \( \alpha \) value, one can achieve a \((1 - \alpha) \cdot 100\%\) confidence that the interval contains the actual mean of the \( y \) values that correspond to the given value of \( x \).

The reason is that there are possible sources of prediction errors in finding the regression line equation. One source occurs when finding the standard error of the estimate \( s_{est} \). Two others are errors made in estimating the slope and the \( y' \) intercept, since the equation of the regression line will change somewhat if different random samples are used when calculating the equation.

**Formula for the Prediction Interval about a Value \( y' \)**

\[
y' - t_{\alpha/2}s_{est}\sqrt{\frac{1 + \frac{1}{n} + \frac{n(x - \bar{x})^2}{\sum x^2 - (\sum x)^2}}}{\sqrt{1 + \frac{1}{n} + \frac{n(x - \bar{x})^2}{\sum x^2 - (\sum x)^2}}}} < y < y' + t_{\alpha/2}s_{est}\sqrt{\frac{1 + \frac{1}{n} + \frac{n(x - \bar{x})^2}{\sum x^2 - (\sum x)^2}}}{\sqrt{1 + \frac{1}{n} + \frac{n(x - \bar{x})^2}{\sum x^2 - (\sum x)^2}}}}
\]

with d.f. = \( n - 2 \).

**Example 10–14**

For the data in Example 10–12, find the 95% prediction interval for the monthly maintenance cost of a machine that is 3 years old.

**Solution**

**STEP 1** Find \( \sum x \), \( \sum x^2 \), and \( \bar{x} \).

\[
\sum x = 20 \quad \sum x^2 = 82 \quad \bar{x} = \frac{20}{6} = 3.3
\]

**STEP 2** Find \( y' \) for \( x = 3 \)

\[
y' = 55.57 + 8.13x
\]

\[
y' = 55.57 + 8.13(3) = 79.96
\]
STEP 3 Find $s_{est}$.

$s_{est} = 6.48$

as shown in Example 10–13.

STEP 4 Substitute in the formula and solve: $t_{a/2} = 2.776$, d.f. = 6 – 2 = 4 for 95%

$$
y' = t_{a/2} s_{est} \sqrt{\frac{1}{n} + \frac{n(x - \bar{X})^2}{\sum x^2 - (\sum x)^2}} < y < y'
$$

$$
+ t_{a/2} s_{est} \sqrt{\frac{1}{n} + \frac{n(x - \bar{X})^2}{\sum x^2 - (\sum x)^2}}
$$

$$
79.96 - (2.776)(6.48) \sqrt{\frac{1}{6} + \frac{6(3 - 3.3)^2}{682 - (20)^2}} < y < 79.96
$$

$$
+ (2.776)(6.48) \sqrt{\frac{1}{6} + \frac{6(3 - 3.3)^2}{682 - (20)^2}}
$$

$$
79.96 - (2.776)(6.48)(1.08) < y < 79.96 + (2.776)(6.48)(1.08)
$$

$$
79.96 - 19.43 < y < 79.96 + 19.43
$$

$$
60.53 < y < 99.39
$$

Hence, one can be 95% confident that the interval $60.53 < y < 99.39$ contains the actual value of $y$.

Exercises 10–5

1. What is meant by the explained variation? How is it computed?

2. What is meant by the unexplained variation? How is it computed?

3. What is meant by the total variation? How is it computed?

4. Define the coefficient of determination.

5. How is the coefficient of determination found?

6. Define the coefficient of nondetermination.

7. How is the coefficient of nondetermination found?

For Exercises 8 through 13, find the coefficients of determination and nondetermination and explain the meaning of each.

8. $r = 0.81$

9. $r = 0.70$

10. $r = 0.45$

11. $r = 0.37$

12. $r = 0.15$

13. $r = 0.05$

14. Define the standard error of the estimate for regression. When can the standard error of the estimate be used to construct a prediction interval about a value $y'$?

15. Compute the standard error of the estimate for Exercise 13 in Section 10–3. The regression line equation was found in Exercise 13 in Section 10–4.

16. Compute the standard error of the estimate for Exercise 14 in Section 10–3. The regression line equation was found in Exercise 14 in Section 10–4.

17. Compute the standard error of the estimate for Exercise 15 in Section 10–3. The regression line equation was found in Exercise 15 in Section 10–4.

18. Compute the standard error of the estimate for Exercise 16 in Section 10–3. The regression line equation was found in Exercise 16 in Section 10–4.

19. For the data in Exercises 13 in Sections 10–3 and 10–4 and 15 in Section 10–5, find the 90% prediction interval when $x = 20$ years.

20. For the data in Exercises 14 in Sections 10–3 and 10–4 and 16 in Section 10–5, find the 95% prediction interval when $x = 1100$.  

\[530\]  
Chapter 10  Correlation and Regression
21. For the data in Exercises 15 in Sections 10–3 and 10–4 and 17 in Section 10–5, find the 90% prediction interval when \( x = 4 \) years.

22. For the data in Exercises 16 in Sections 10–3 and 10–4 and 18 in Section 10–5, find the 98% prediction interval when \( x = 47 \) years.

The previous sections explained the concepts of simple linear regression and correlation. In simple linear regression, the regression equation contains one independent variable \( x \) and one dependent variable \( y' \) and is written as

\[
y' = a + bx
\]

where \( a \) is the \( y' \) intercept and \( b \) is the slope of the regression line.

In multiple regression, there are several independent variables and one dependent variable, and the equation is

\[
y' = a + b_1x_1 + b_2x_2 + \cdots + b_kx_k
\]

where \( x_1, x_2, \ldots, x_k \) are the independent variables.

For example, suppose a nursing instructor wishes to see whether there is a relationship between a student’s grade-point average, age, and score on the state board nursing examination. The two independent variables are GPA (denoted by \( x_1 \)) and age (denoted by \( x_2 \)). The instructor will collect the data for all three variables for a sample of nursing students. Rather than conduct two separate simple regression studies, one using the GPA and state board scores and another using ages and state board scores, the instructor can conduct one study using multiple regression analysis with two independent variables—GPA and ages—and one dependent variable—state board scores.

A multiple regression correlation \( R \) can also be computed to determine if a significant relationship exists between the independent variables and the dependent variable. Multiple regression analysis is used when a statistician thinks there are several independent variables contributing to the variation of the dependent variable. This analysis then can be used to increase the accuracy of predictions for the dependent variable over one independent variable alone.
Two other examples for multiple regression analysis are when a store manager wants to see whether the amount spent on advertising and the amount of floor space used for a display affect the amount of sales of a product, and when a sociologist wants to see whether the amount of time children spend watching television and playing video games is related to their weight. Multiple regression analysis can also be conducted by using more than two independent variables, denoted by $x_1, x_2, x_3, \ldots, x_m$. Since these computations are quite complicated and for the most part would be done on a computer, this chapter will show the computations for two independent variables only.
For example, the nursing instructor wishes to see whether a student’s grade-point average and age are related to the student’s score on the state board nursing examination. She selects five students and obtains the following data.

<table>
<thead>
<tr>
<th>Student</th>
<th>GPA $x_1$</th>
<th>Age $x_2$</th>
<th>State board score $y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>3.2</td>
<td>22</td>
<td>550</td>
</tr>
<tr>
<td>B</td>
<td>2.7</td>
<td>27</td>
<td>570</td>
</tr>
<tr>
<td>C</td>
<td>2.5</td>
<td>24</td>
<td>525</td>
</tr>
<tr>
<td>D</td>
<td>3.4</td>
<td>28</td>
<td>670</td>
</tr>
<tr>
<td>E</td>
<td>2.2</td>
<td>23</td>
<td>490</td>
</tr>
</tbody>
</table>

The multiple regression equation obtained from the data is

$$y' = -44.572 + 87.679x_1 + 14.519x_2$$

If a student has a GPA of 3.0 and is 25 years old, her predicted state board score can be computed by substituting these values in the equation for $x_1$ and $x_2$, respectively, as shown.

$$y' = -44.572 + 87.679(3.0) + 14.519(25)$$
$$= 581.44 \text{ or } 581$$

Hence, if a student has a GPA of 3.0 and is 25 years old, the student’s predicted state board score is 581.

A multiple regression equation with two independent variables ($x_1$ and $x_2$) and one dependent variable would have the form

$$y' = a + b_1x_1 + b_2x_2$$

A multiple regression with three independent variables ($x_1$, $x_2$, and $x_3$) and one dependent variable would have the form

$$y' = a + b_1x_1 + b_2x_2 + b_3x_3$$

The General Form of the Multiple Regression Equation

The general form of the multiple regression equation with $k$ independent variables is

$$y' = a + b_1x_1 + b_2x_2 + \cdots + b_kx_k$$

The $x$’s are the independent variables. The value for $a$ is more or less an intercept, although a multiple regression equation with two independent variables constitutes a plane rather than a line. The $b$’s are called partial regression coefficients. Each $b$ represents the amount of change in $y'$ for one unit of change in the corresponding $x$ value when the other $x$ values are held constant. In the example just shown, the regression equation was $y' = -44.572 + 87.679x_1 + 14.519x_2$. In this case, for each unit of change in the student’s GPA, there is a change of 87.679 units in the state board score with the student’s age $x_2$ being held constant. And for each unit of change in $x_2$ (the student’s age), there is a change of 14.519 units in the state board score with the GPA held constant.
Assumptions for Multiple Regression

The assumptions for multiple regression are similar to those for simple regression.

1. For any specific value of the independent variable, the values of the \( y \) variable are normally distributed. (This is called the normality assumption.)

2. The variances (or standard deviations) for the \( y \) variables are the same for each value of the independent variable. (This is called the equal-variance assumption.)

3. There is a linear relationship between the dependent variable and the independent variables. (This is called the linearity assumption.)

4. The independent variables are not correlated. (This is called the nonmulticolinearity assumption.)

5. The values for the \( y \) variables are independent. (This is called the independence assumption.)

In multiple regression, as in simple regression, the strength of the relationship between the independent variables and the dependent variable is measured by a correlation coefficient. This multiple correlation coefficient is symbolized by \( R \). The value of \( R \) can range from 0 to +1; \( R \) can never be negative. The closer to +1, the stronger the relationship; the closer to 0, the weaker the relationship. The value of \( R \) takes into account all the independent variables and can be computed by using the values of the individual correlation coefficients. The formula for the multiple correlation coefficient when there are two independent variables is shown next.

Formula for the Multiple Correlation Coefficient

The formula for \( R \) is

\[
R = \sqrt{r_{y1}^2 + r_{y2}^2 - 2r_{y1} \cdot r_{y2} \cdot r_{x1x2}} \cdot \frac{1}{1 - r_{x1x2}^2}
\]

where \( r_{y1} \) is the value of the correlation coefficient for variables \( y \) and \( x_1 \); \( r_{y2} \) is the value of the correlation coefficient for variables \( y \) and \( x_2 \); and \( r_{x1x2} \) is the value of the correlation coefficient for variables \( x_1 \) and \( x_2 \).

In this case, \( R \) is 0.989, as shown in Example 10–15. The multiple correlation coefficient is always higher than the individual correlation coefficients. For this specific example, the multiple correlation coefficient is higher than the two individual correlation coefficients computed by using grade-point average and state board scores (\( r_{y1} = 0.845 \)) or age and state board scores (\( r_{y2} = 0.791 \)). Note: \( r_{x1x2} = 0.371 \).

Example 10–15

For the data regarding state board scores, find the value of \( R \).

Solution

The values of the correlation coefficients are

\[
\begin{align*}
    r_{y1} &= 0.845 \\
    r_{y2} &= 0.791 \\
    r_{x1x2} &= 0.371
\end{align*}
\]
Substituting in the formula, one gets

\[
R = \sqrt{r_{yx_1}^2 + r_{yx_2}^2 - 2r_{yx_1} \cdot r_{yx_2} \cdot r_{yx_3}} \div 1 - r_{yx_5}^2
\]

\[
= \sqrt{(0.845)^2 + (0.791)^2 - 2(0.845)(0.791)(0.371)} \div 1 - 0.371^2
\]

\[
= \sqrt{0.8437569 - 0.862359} = \sqrt{0.9784288} = 0.989
\]

Hence, the correlation between a student’s grade-point average and age with the student’s score on the nursing state board examination is 0.989. In this case, there is a strong relationship among the variables; the value of \( R \) is close to 1.00.

As with simple regression, \( R^2 \) is the coefficient of multiple determination, and it is the amount of variation explained by the regression model. The expression \( 1 - R^2 \) represents the amount of unexplained variation, called the error or residual variation. Since \( R = 0.989 \), \( R^2 = 0.978 \) and \( 1 - R^2 = 1 - 0.978 = 0.022 \).

An \( F \) test is used to test the significance of \( R \). The hypotheses are

\[
H_0: \rho = 0 \quad \text{and} \quad H_1: \rho \neq 0
\]

where \( \rho \) represents the population correlation coefficient for multiple correlation.

### Testing the Significance of \( R \)

#### F Test for Significance of \( R \)

The formula for the \( F \) test is

\[
F = \frac{R^2/k}{(1 - R^2)/(n - k - 1)}
\]

where \( n \) is the number of data groups \((x_1, x_2, \ldots, y)\) and \( k \) is the number of independent variables.

The degrees of freedom are d.f.N. = \( n - k \) and d.f.D. = \( n - k - 1 \).

#### Example 10–16

Test the significance of the \( R \) obtained in Example 10–15 at \( \alpha = 0.05 \).

**Solution**

\[
F = \frac{R^2/k}{(1 - R^2)/(n - k - 1)}
\]

\[
= \frac{0.978/2}{(1 - 0.978)/(5 - 2 - 1)} = \frac{0.489}{0.011} = 44.45
\]

The critical value obtained from Table H with \( \alpha = 0.05 \), d.f.N. = 3, and d.f.D. = \( 5 - 2 - 1 = 2 \) is 19.16. Hence, the decision is to reject the null hypothesis and conclude that there is a significant relationship among the student’s GPA, age, and score on the nursing state board examination.
Adjusted $R^2$

Since the value of $R^2$ is dependent on $n$ (the number of data pairs) and $k$ (the number of variables), statisticians also calculate what is called an **adjusted $R^2$**, denoted by $R_{adj}^2$. This is based on the number of degrees of freedom.

### Formula for the Adjusted $R^2$

The formula for the adjusted $R^2$ is

$$R_{adj}^2 = 1 - \frac{(1 - R^2)(n - 1)}{n - k - 1}$$

The adjusted $R^2$ is smaller than $R^2$ and takes into account the fact that when $n$ and $k$ are approximately equal, the value of $R$ may be artificially high, due to sampling error rather than a true relationship among the variables. This occurs because the chance variations of all the variables are used in conjunction with each other to derive the regression equation. Even if the individual correlation coefficients for each independent variable and the dependent variable were all zero, the multiple correlation coefficient due to sampling error could be higher than zero.

Hence, both $R^2$ and $R_{adj}^2$ are usually reported in a multiple regression analysis.

**Example 10–17**

Calculate the adjusted $R^2$ for the data in Example 10–16. The value for $R$ is 0.989.

**Solution**

$$R_{adj}^2 = 1 - \frac{(1 - R^2)(n - 1)}{n - k - 1}$$

$$= 1 - \frac{(1 - 0.989^2)(5 - 1)}{5 - 2 - 1}$$

$$= 1 - 0.043758$$

$$= 0.956$$

In this case, when the number of data pairs and the number of independent variables are accounted for, the adjusted multiple coefficient of determination is 0.956.

### Exercises 10–6

1. Explain the similarities and differences between simple linear regression and multiple regression.

2. What is the general form of the multiple regression equation? What does the $a$ represent? What do the $b$‘s represent?

3. Why would a researcher prefer to conduct a multiple regression study rather than separate regression studies using one independent variable and the dependent variable?

4. What are the assumptions for multiple regression?

5. How do the values of the individual correlation coefficients compare to the value of the multiple correlation coefficient?

6. A researcher has determined that a significant relationship exists among an employee’s age $x_1$, grade-point average $x_2$, and income $y$. The multiple regression equation is $y' = -34,127 + 132x_1 + 20,805x_2$. Predict the income of a person who is 32 years old and has a GPA of 3.4.

7. A manufacturer found that a significant relationship exists among the number of hours an assembly line
employee works per shift $x_1$, the total number of items produced $x_2$, and the number of defective items produced $y$. The multiple regression equation is $y' = 9.6 + 2.2x_1 - 1.08x_2$. Predict the number of defective items produced by an employee who has worked 9 hours and produced 24 items.

8. A real estate agent found that there is a significant relationship among the number of acres on a farm $x_1$, the number of rooms in the farmhouse $x_2$, and the selling price in thousands of dollars $y$ of farms in a specific area. The regression equation is $y' = 44.9 - 0.0266x_1 + 7.56x_2$. Predict the selling price of a farm that has 371 acres and a farmhouse with six rooms.

9. An educator has found a significant relationship among a college graduate’s IQ $x_1$, score on the verbal section of the SAT $x_2$, and income for the first year following graduation from college $y$. Predict the income of a college graduate whose IQ is 120 and verbal SAT score is 650. The regression equation is $y' = 5000 + 97x_1 + 35x_2$.

10. A medical researcher found a significant relationship among a person’s age $x_1$, cholesterol level $x_2$, sodium level of the blood $x_3$, and systolic blood pressure $y$. The regression equation is $y' = 97.7 + 0.691x_1 + 219x_2 - 299x_3$. Predict the blood pressure of a person who is 35 years old and has a cholesterol level of 194 milligrams per deciliter (mg/dl) and a sodium blood level of 142 milliequivalents per liter (mEq/l).

11. Explain the meaning of the multiple correlation coefficient $R$.

12. What is the range of values $R$ can assume?

13. Define $R^2$ and $R^2_{adj}$.

14. What are the hypotheses used to test the significance of $R$?

15. What test is used to test the significance of $R$?

16. What is the meaning of the adjusted $R^2$? Why is it computed?

---

### Technology Step by Step

#### MINITAB Step by Step: Multiple Regression

In Example 10–15, is there a correlation between a student’s score and her or his age and grade-point average?

1. Enter the data for the example into three columns of MINITAB. Name the columns GPA, AGE, and SCORE.

2. Click Stat>Regression> Regression.

3. Double-click on C3 SCORE, the response variable.

4. Double-click C1 GPA, then C2 AGE.

5. Click on [Storage].
   a) Check the box for Residuals.
   b) Check the box for Fits.

6. Click [OK] twice.

**Regression Analysis: SCORE versus GPA, AGE**

The regression equation is

$$
SCORE = -44.81 + 87.6 \times GPA + 14.5 \times AGE
$$

<table>
<thead>
<tr>
<th>Predictor</th>
<th>Coef</th>
<th>SE Coef</th>
<th>T</th>
<th>P</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constant</td>
<td>-44.81</td>
<td>69.25</td>
<td>-0.65</td>
<td>0.584</td>
</tr>
</tbody>
</table>

---

10–45
The test statistic and $P$-value are 45.93 and 0.021, respectively. Since the $P$-value is less than $\alpha$, reject the null hypothesis. There is enough evidence in the sample to conclude the scores are related to age and grade-point average.

The TI-83 Plus does not have a built-in function for multiple regression. However, the downloadable program named MULREG is available on your CD and Online Learning Center. Follow the instructions with your CD for downloading the program.

**Finding a Multiple Regression Equation**

1. Enter the sets of data values into $L_1$, $L_2$, $L_3$, etc. Make note of which lists contain the independent variables and which list contains the dependent variable as well as how many data values are in each list.
2. Press PRGM, move the cursor to the program named MULREG, and press ENTER twice.
3. Type the number of independent variables and press ENTER.
4. Type the number of cases for each variable and press ENTER.
5. Type the name of the list which contains the data values for the first independent variable and press ENTER. Repeat this for all independent variables and the dependent variable.
6. The program will show the regression coefficients.
7. Press ENTER to see the values of $R^2$ and adjusted $R^2$.
8. Press ENTER to see the values of the $F$ test statistics and the $P$-value.

Find the multiple regression equation for these data used in this section:

<table>
<thead>
<tr>
<th>Student</th>
<th>GPA $x_1$</th>
<th>Age $x_2$</th>
<th>State board score $y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>3.2</td>
<td>22</td>
<td>550</td>
</tr>
<tr>
<td>B</td>
<td>2.7</td>

<td>28</td>
<td>670</td>
</tr>
<tr>
<td>E</td>
<td>2.2</td>
<td>23</td>
<td>490</td>
</tr>
</tbody>
</table>

The coefficient of determination is 97.9% and the adjusted coefficient of determination is 95.7%.
Multiple Regression

These instructions use data from the nursing examination example discussed at the beginning of Section 10–6.

1. Enter the data from the example into three separate columns of a new worksheet. GPAs in cells A1:A5, ages in cells B1:B5, and scores in cells C1:C5.
2. Select Tools>Data Analysis>Regression.
3. Select cells C1:C5 for the Input Y Range.
5. Click [OK].

Regression Analysis: SCORE versus GPA, AGE

The regression equation is

\[
\text{SCORE} = -44.8 + 87.6 \text{ GPA} + 14.5 \text{ AGE}
\]

The session window shows the correlation coefficient for each pair of variables. The multiple correlation coefficient is significant at 0.021. Ninety-six percent of the variation from the mean is explained by regression. The regression equation is \( \text{SCORE} = -44.8 + 87.6\text{GPA} + 14.5\text{AGE} \).
Many relationships among variables exist in the real world. One way to determine whether a relationship exists is to use the statistical techniques known as correlation and regression. The strength and direction of the relationship are measured by the value of the correlation coefficient. It can assume values between and including $+1$ and $-1$. The closer the value of the correlation coefficient is to $+1$ or $-1$, the stronger the linear relationship is between the variables. A value of $+1$ or $-1$ indicates a perfect linear relationship. A positive relationship between two variables means that for small values of the independent variable, the values of the dependent variable will be small, and that for large values of the independent variable, the values of the dependent variable will be large. A negative relationship between two variables means that for small values of the independent variable, the values of the dependent variable will be large, and that for large values of the independent variable, the values of the dependent variable will be small.

Relationships can be linear or curvilinear. To determine the shape, one draws a scatter plot of the variables. If the relationship is linear, the data can be approximated by a straight line, called the regression line, or the line of best fit. The closer the value of $r$ is to $+1$ or $-1$, the closer the points will fit the line.

In addition, relationships can be multiple. That is, there can be two or more independent variables and one dependent variable. A coefficient of correlation and a regression equation can be found for multiple relationships, just as they can be found for simple relationships.

The coefficient of determination is a better indicator of the strength of a relationship than the correlation coefficient. It is better because it identifies the percentage of variation of the dependent variable that is directly attributable to the variation of the independent variable. The coefficient of determination is obtained by squaring the correlation coefficient and converting the result to a percentage.

Another statistic used in correlation and regression is the standard error of the estimate, which is an estimate of the standard deviation of the $y$ values about the predicted $y'$ values. The standard error of the estimate can be used to construct a prediction interval about a specific value point estimate $y'$ of the mean of the $y$ values for a given value of $x$.

Finally, remember that a significant relationship between two variables does not necessarily mean that one variable is a direct cause of the other variable. In some cases this is true, but other possibilities that should be considered include a complex relationship involving other (perhaps unknown) variables, a third variable interacting with both variables, or a relationship due solely to chance.

**Important Formulas**

Formula for the correlation coefficient:

$$ r = \frac{n(\sum xy) - (\sum x)(\sum y)}{\sqrt{n(\sum x^2) - (\sum x)^2} \sqrt{n(\sum y^2) - (\sum y)^2}} $$

Formula for the $t$ test for the correlation coefficient:

$$ t = r \sqrt{\frac{n - 2}{1 - r^2}} \quad \text{d.f.} = n - 2 $$

The regression line equation: $y' = a + bx$, where

$$ a = \frac{(\sum y)(\sum x^2) - (\sum x)(\sum xy)}{n(\sum x^2) - (\sum x)^2} $$

$$ b = \frac{n(\sum xy) - (\sum x)(\sum y)}{n(\sum x^2) - (\sum x)^2} $$

Formula for the standard error of the estimate:

$$ s_{est} = \sqrt{\frac{\sum (y - y')^2}{n - 2}} $$

or

$$ s_{est} = \sqrt{\frac{\sum y^2 - a \sum y - b \sum xy}{n - 2}} $$

Formula for the prediction interval for a value $y'$:

$$ y' - t_{a/2}s_{est} \sqrt{1 + \frac{1}{n} + \frac{n(x - \bar{x})^2}{n \sum x^2 - (\sum x)^2}} \leq y' \leq y' + t_{a/2}s_{est} \sqrt{1 + \frac{1}{n} + \frac{n(x - \bar{x})^2}{n \sum x^2 - (\sum x)^2}} $$

d.f. = $n - 2$

Formula for the multiple correlation coefficient:

$$ R = \sqrt{\frac{\sum y^2 - \sum y'y''}{\sum y'^2}} $$

Formula for the $F$ test for the multiple correlation coefficient:

$$ F = \frac{R^2}{1 - R^2}/(n - k - 1) $$

with d.f.N = $n - k$ and d.f.D = $n - k - 1$.

Formula for the adjusted $R^2$:

$$ R^2_{adj} = 1 - \left[ \frac{(1 - R^2)(n - 1)}{n - k - 1} \right] $$

**Review Exercises**

For Exercises 1 through 7, do a complete regression analysis by performing the following steps.

- **a.** Draw the scatter plot.
- **b.** Compute the value of the correlation coefficient.
- **c.** Test the significance of the correlation coefficient at $\alpha = 0.01$, using Table I.
- **d.** Determine the regression line equation.
- **e.** Plot the regression line on the scatter plot.
- **f.** Predict $y'$ for a specific value of $x$.

1. These data represent the number of hits and the number of strikeouts for 15 players on a college baseball team. If there is a significant relationship between the variables, predict the number of strikeouts a baseball player is likely to have if he has 30 hits.

8. For Exercise 4, find the standard error of the estimate.
9. For Exercise 5, find the standard error of the estimate.
10. For Exercise 6, find the standard error of the estimate.
11. For Exercise 4, find the 90% prediction interval for time when the speed is 72 words per minute.
12. For Exercise 5, find the 95% prediction interval for pressure when the number of grams is 8.
13. (Opt.) A study found a significant relationship among a person’s years of experience on a particular job, the number of work days missed per month, and the person’s age. The regression equation is $y = 12.8 + 2.09x_1 + 0.423x_2$. Predict a person’s age if he or she has been employed for 4 years and has missed 2 work days a month.
14. (Opt.) Find $R$ when $r_{x_1} = 0.681$ and $r_{x_2} = 0.872$ and $r_{x_1,x_2} = 0.746$.
15. (Opt.) Find $R^2_{adj}$ when $R = 0.873$, $n = 10$, and $k = 3.$

Do Dust Storms Affect Respiratory Health?—Revisited

The researchers correlated the dust pollutant levels in the atmosphere and the number of daily emergency room visits for several respiratory disorders, such as bronchitis, sinusitis, asthma, and pneumonia. Using the Pearson correlation coefficient, they found overall a significant but low correlation, $r = 0.13$, for bronchitis visits only. However, they found a much higher correlation value for sinusitis, $P$-value $= 0.08$, when pollutant levels exceeded maximums set by the Environmental Protection Agency (EPA). In addition, they found statistically significant correlation coefficients $r = 0.94$ for sinusitis visits and $r = 0.74$ for upper-respiratory-tract infection visits 2 days after the dust pollutants exceeded the maximum levels set by the EPA.
Data Analysis

The Data Bank is found in Appendix D, or on the World Wide Web by following links from www.mhhe.com/math/stat/bluman/.

1. From the Data Bank, choose two variables that might be related: e.g., IQ and educational level; age and cholesterol level; exercise and weight; or weight and systolic pressure. Do a complete correlation and regression analysis by performing the following steps. Select a random sample of at least 10 subjects.
   a. Draw a scatter plot.
   b. Compute the correlation coefficient.
   c. Test the hypothesis $H_0: r = 0$.
   d. Find the regression line equation.
   e. Summarize the results.

2. Repeat Exercise 1, using Data Set XI in Appendix D. Let $x =$ the number of miles and $y =$ the number of vehicles operated. If you are using a TI-83 Plus calculator or a computer program, use all the data values; otherwise, select a sample of 10 values.

3. Repeat Exercise 1, using the data from Data Set XI in Appendix D and let $x =$ the number of miles and $y =$ the number of stations. If you are using a TI-83 Plus calculator or a computer program, use all the data values; otherwise, select a sample of 10 values.

Chapter Quiz

Determine whether each statement is true or false. If the statement is false, explain why.

1. A negative relationship between two variables means that for the most part, as the $x$ variable increases, the $y$ variable increases.

2. A correlation coefficient of $-1$ implies a perfect linear relationship between the variables.

3. Even if the correlation coefficient is high or low, it may not be significant.

4. When the correlation coefficient is significant, one can assume $x$ causes $y$.

5. It is not possible to have a significant correlation by chance alone.

6. In multiple regression, there are several dependent variables and one independent variable.

Select the best answer.

7. The strength of the relationship between two variables is determined by the value of $r$.
   a. $r$  
   b. $a$  
   c. $x$  
   d. $s_{xy}$

8. To test the significance of $r$, a(n) ______ test is used.
   a. $t$  
   b. $F$  
   c. $X^2$  
   d. None of the above

9. The test of significance for $r$ has ______ degrees of freedom.
   a. $1$  
   b. $n$  
   c. $n - 1$  
   d. $n - 2$

10. The equation of the regression line used in statistics is
    a. $x = a + by$  
    b. $y = bx + a$  
    c. $y' = a + bx$  
    d. $x = ay + b$

11. The coefficient of determination is
    a. $r$  
    b. $r^2$  
    c. $a$  
    d. $b$

Complete the following statements with the best answer.

12. A statistical graph of two variables is called a(n) ______.

13. The $x$ variable is called the ______ variable.

14. The range of $r$ is from ______ to ______.

15. The sign of $r$ and ______ will always be the same.

16. The regression line is called the ______.

17. If all the points fall on a straight line, the value of $r$ will be ______ or ______.

For Exercises 18 through 21, do a complete regression analysis.

a. Draw the scatter plot.

b. Compute the value of the correlation coefficient.

For Exercises 18 through 21, do a complete regression analysis.

For Exercises 18 through 21, do a complete regression analysis.

a. Draw the scatter plot.

b. Compute the value of the correlation coefficient.

For Exercises 18 through 21, do a complete regression analysis.

a. Draw the scatter plot.

b. Compute the value of the correlation coefficient.

c. Test the significance of the correlation coefficient at $\alpha = 0.05$.

18. The relationship between a father’s age and the number of children he has is studied. The data are shown here. If there is a significant relationship, predict the number of children of a father whose age is 35.

<table>
<thead>
<tr>
<th>Father’s age $x$</th>
<th>19</th>
<th>21</th>
<th>27</th>
<th>20</th>
<th>25</th>
<th>31</th>
<th>32</th>
<th>38</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of children $y$</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>0</td>
<td>1</td>
<td>4</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

19. A study is conducted to determine the relationship between a driver’s age and the number of
accidents he or she has over a 1-year period. The data are shown here. If there is a significant relationship, predict the number of accidents of a driver who is 64.

<table>
<thead>
<tr>
<th>Driver's age x</th>
<th>63</th>
<th>65</th>
<th>60</th>
<th>62</th>
<th>66</th>
<th>67</th>
<th>59</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of accidents y</td>
<td>2</td>
<td>3</td>
<td>1</td>
<td>0</td>
<td>3</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

20. A researcher desires to know if the age of a child is related to the number of cavities he or she has. The data are shown here. If there is a significant relationship, predict the number of cavities for a child of 11.

<table>
<thead>
<tr>
<th>Age of child x</th>
<th>68</th>
<th>9</th>
<th>1</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>1</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of cavities y</td>
<td>2</td>
<td>1</td>
<td>3</td>
<td>4</td>
<td>6</td>
<td>5</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

21. A study is conducted with a group of dieters to see if the number of grams of fat each consumes per day is related to cholesterol level. The data are shown here. If there is a significant relationship, predict the cholesterol level of a dieter who consumes 8.5 grams of fat per day.

<table>
<thead>
<tr>
<th>Fat grams x</th>
<th>6.8</th>
<th>5.5</th>
<th>8.2</th>
<th>10</th>
<th>8.6</th>
<th>9.1</th>
<th>8.6</th>
<th>10.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cholesterol level y</td>
<td>183</td>
<td>201</td>
<td>193</td>
<td>283</td>
<td>222</td>
<td>250</td>
<td>190</td>
<td>218</td>
</tr>
</tbody>
</table>

22. For Exercise 20, find the standard error of the estimate.

23. For Exercise 21, find the standard error of the estimate.

24. For Exercise 20, find the 90% prediction interval of the number of cavities for a 7-year-old.

25. For Exercise 21, find the 95% prediction interval of the cholesterol level of a person who consumes 10 grams of fat.

26. (Opt.) A study was conducted, and a significant relationship was found among the number of hours a teenager watches television per day \( x_1 \), the number of hours the teenager talks on the telephone per day \( x_2 \), and the teenager’s weight \( y \). The regression equation is \( y = 98.7 + 3.82x_1 + 6.51x_2 \). Predict a teenager’s weight if she averages 3 hours of TV and 1.5 hours on the phone per day.

27. (Opt.) Find \( R \) when \( r_{xy} = 0.561 \) and \( r_{yx} = 0.714 \) and \( r_{x,y} = 0.625 \).

28. (Opt.) Find \( R_{adj}^2 \) when \( R = 0.774 \), \( n = 8 \), and \( k = 2 \).

### Critical Thinking Challenges

When the points in a scatter plot show a curvilinear trend rather than a linear trend, statisticians have methods of fitting curves rather than straight lines to the data, thus obtaining a better fit and a better prediction model. One type of curve that can be used is the logarithmic regression curve. The data shown are the number of items of a new product sold over a period of 15 months at a certain store. Notice that sales rise during the beginning months and then level off later on.

<table>
<thead>
<tr>
<th>Month x</th>
<th>1</th>
<th>3</th>
<th>6</th>
<th>8</th>
<th>10</th>
<th>12</th>
<th>15</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of items sold y</td>
<td>10</td>
<td>12</td>
<td>15</td>
<td>19</td>
<td>20</td>
<td>21</td>
<td>21</td>
</tr>
</tbody>
</table>

1. Draw the scatter plot for the data.

2. Find the equation of the regression line.

3. Describe how the line fits the data.

4. Using the log key on your calculator, transform the \( x \) values into \( \log x \) values.

5. Using the \( \log x \) values instead of the \( x \) values, find the equation of \( a \) and \( b \) for the regression line.

6. Next, plot the curve \( y = a + b \log x \) on the graph.

7. Compare the line \( y = a + bx \) with the curve \( y = a + b \log x \) and decide which one fits the data better.

8. Compute \( r \), using the \( x \) and \( y \) values; then compute \( r \), using the \( \log x \) and \( y \) values. Which is higher?

9. In your opinion, which (the line or the logarithmic curve) would be a better predictor for the data? Why?

### Data Projects

Where appropriate, use MINITAB, the TI-83 Plus, or a computer program of your choice to complete the following exercises.

1. Select two variables that might be related, such as the age of a person and the number of cigarettes the person smokes, or the number of credits a student has and the number of hours the student watches television. Sample at least 10 people.
   a. Write a brief statement as to the purpose of the study.
   b. Define the population.
   c. State how the sample was selected.
   d. Show the raw data.
Section 10–7 Summary

545

e. Draw a scatter plot for the data values.
f. Write a statement analyzing the scatter plot.
g. Compute the value of the correlation coefficient.
h. Test the significance of $r$ (State the hypotheses, select $\alpha$, find the critical values, make the decision, and analyze the results.)
i. Find the equation of the regression line and draw it on the scatter plot. (Note: Even if $r$ is not significant, complete this step.)
j. Summarize the overall results.

2. For the data in Exercise 1, use MINITAB to answer these.
a. Does a linear correlation exist between $x$ and $y$?
b. If so, find the regression equation.
c. Explain how good a model the regression equation is by finding the coefficient of determination and coefficient of correlation and interpreting the strength of these values.
d. Find the prediction interval for $y$. Use the $\alpha$ value that you selected in Exercise 1.
